CERTIFYING A FINAL ENVIRONMENTAL IMPACT REPORT FOR THE PROPOSED SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT.

MOVED, that the San Francisco Planning Commission (hereinafter "Commission") hereby CERTIFIES the Environmental Impact Report identified as Case No. 2007.0427E for the San Joaquin Regional Water Quality Improvement Project (SJRWQIP), located in San Joaquin County (hereinafter "Project"), based upon the following findings:

1. The City and County of San Francisco, acting through the Planning Department (hereinafter "Department") fulfilled all procedural requirements of the California Environmental Quality Act (Cal. Pub. Res. Code Section 21000 *et seq.*, hereinafter "CEQA"), the State CEQA Guidelines (Cal. Admin. Code Title 14, Section 15000 *et seq.*, (hereinafter "CEQA Guidelines") and Chapter 31 of the San Francisco Administrative Code (hereinafter "Chapter 31").

   A. The Department determined that an Environmental Impact Report (hereinafter "EIR") was required and in accordance with 15082 of the CEQA Guidelines, the Department prepared a Notice of Preparation (NOP) of an EIR and conducted a scoping meeting (see Draft EIR, Appendix A). The NOP was circulated to local, state, and federal agencies and to other interested parties on May 17, 2007, initiating a public comment period that extended through June 18, 2007. Pursuant to CEQA Guidelines Section 15083, the Department held one public scoping meeting in Tracy on June 6, 2007. The purpose of the meeting was to present the proposed SJRWQIP to the public and receive public input regarding the

proposed scope of the EIR analysis. A scoping report was prepared to summarize the public scoping process and the comments received in response to the NOP, and the report is included in Appendix A of the Draft EIR.

B. On August 25, 2008, the Department published the Draft Environmental Impact Report (hereinafter "DEIR") and provided public notice in a newspaper of general circulation of the availability of the DEIR for public review and comment and of the date and time of the public hearings on the DEIR; this notice was mailed to the Department's list of persons requesting such notice and other interested parties.

C. Notices of availability of the DEIR and of the date and time of the public hearings were posted at the project sites, the Tesla Portal site and the Thomas Shaft site, in San Joaquin County by Department staff on August 25, 2008.

D. On August 25, 2008, copies of the DEIR were mailed or otherwise delivered to a list of persons requesting it, to those noted on the distribution list in the DEIR, and to government agencies, the latter both directly and through the State Clearinghouse. The DEIR was posted on the Department's website.

E. Notice of Completion was filed with the State Secretary of Resources via the State Clearinghouse on August 25, 2008.

2. The DEIR was circulated to local, state, and federal agencies and to interested organizations and individuals for review and comment on August 25, 2008 for a 45-day public review period. The public review period closed on October 8, 2008. Two duly advertised public hearings on the DEIR to accept written or oral comments were held; one hearing was held in Tracy on September 16, 2008, and a second hearing was held in San Francisco on September 18, 2008. The Commission acknowledges and endorses the supplemental public hearing that the Environmental Review Officer's delegate conducted in Tracy in order to allow potentially affected members of the public to present oral comments at a convenient location. The public hearings transcripts are in the Project record, and Planning Department staff reported to the Commission on the public hearing in Tracy.

3. The Department prepared responses to comments on environmental issues received at the public hearings and in writing during the public review period for the DEIR, prepared revisions to the text of the DEIR in response to comments received or based on additional information that became available during the public review period, and corrected errors in the DEIR. This material was presented in a Draft Comments and Responses document

(hereinafter "C&R"), published on December 4, 2008, distributed to the Commission and all parties who commented on the DEIR, and made available to others upon request at Department offices and on the Department's website.

4. A Final Environmental Impact Report (hereinafter "FEIR") has been prepared by the Department, consisting of the DEIR, any consultations and comments received during the review process, any additional information that became available, and the Summary of Comments and Responses, all as required by law.

5. Project files on the FEIR have been made available for review by the Commission and the public. These files are available for public review at the Department offices at 1650 Mission Street, and are part of the record before the Commission. Linda Avery is the custodian of records. Copies of the DEIR and associated reference materials as well as the C&R document are also available for review at public libraries in San Francisco and San Joaquin Counties.

6. The Commission, in certifying the completion of said FEIR, hereby does find that the SJRWQIP described in the DEIR, will not result in project-specific significant environmental effects that could not be mitigated to a less than significant level with implementation of mitigation measures. Because the project is part of the Water System Improvement Program (WSIP, the project would contribute to the following significant and unavoidable effects on the environment identified for the WSIP:

   Significant and Unavoidable WSIP Water Supply Impacts:

   - The proposed water supply and system operations would reduce stream flows and alter the stream hydrograph along Alameda Creek below the Alameda Creek Diversion Dam in the Alameda Creek watershed in Alameda County and result in a significant and unavoidable impact on stream flow in Alameda Creek between the diversion dam and the confluence with Calaveras Creek;

   - The proposed water supply and system operations would result in a potentially significant and unavoidable impact in the Peninsula watershed on fishery resources in Crystal Springs Reservoir in San Mateo County; and

   - The Program would indirectly contribute to potentially significant and unavoidable environmental impacts caused by growth in the SFPUC service area, as identified in the planning documents and associated environmental documents for the affected jurisdictions.

7. The Commission reviewed and considered the FEIR and hereby does find that the contents of said report and the procedures through which the FEIR was prepared, publicized and reviewed comply with the provisions of CEQA, the CEQA Guidelines and Chapter 31 of the San Francisco Administrative Code.

8. The Planning Commission hereby does find that the FEIR concerning File No. 2007.0427E, San Joaquin Regional Water Quality Improvement Project, reflects the independent judgment and analysis of the City and County of San Francisco, is adequate, accurate and objective, and that the C&R contains no significant revisions to the DEIR, and hereby does CERTIFY THE COMPLETION of said FEIR in compliance with CEQA and the CEQA Guidelines.

I hereby certify that the foregoing Motion was ADOPTED by the Planning Commission at its duly noticed regular meeting of December 18, 2008.

ACTION: Certification of a Final Environmental Impact Report for the Proposed San Joaquin Regional Water Quality Improvement Project

AGENDA ITEM
Public Utilities Commission
City and County of San Francisco

DEPARTMENT Infrastructure Division AGENDA NO.

MEETING DATE December 18, 2008

SUMMARY OF PROPOSED COMMISSION ACTION

Approve Water System Improvement Program (WSIP)-funded Project No. CUW38401, Tesla Treatment Facility and WSIP-funded Project No. CUW36401, Lawrence Livermore Water Quality Improvements; **Adopt** California Environmental Quality Act (CEQA) Findings, including a statement of overriding considerations and the Mitigation Monitoring and Reporting Program (MMRP) and authorize a request to the Board of Supervisors to adopt the same; and **Authorize** staff to issue a Notice to Proceed (NTP) for Phase 2A – Final Design-Build, Long Lead Item Procurement and Fabrication of Material for DB116, Tesla Treatment Facility, and to advertise a construction contract for Lawrence Livermore Water Quality Improvements.

DESCRIPTION OF PROJECT ACTION

Project Approval

The proposed project would improve already-existing uses (i.e., water treatment) at two sites. The project evaluated in the EIR titled San Joaquin Regional Water Quality Improvement Project (SFRWQIP), is listed as three separate projects in the WSIP Program EIR (PEIR): the Tesla Portal Disinfection Facility, the Hetch Hetchy Advanced Disinfection, and the Lawrence Livermore Supply Improvements. The two projects at the Tesla Portal site (the Tesla Portal Disinfection Facility and the Hetch Hetchy Advanced Disinfection) were combined into one project now called the Tesla Treatment Facility, and the Lawrence Livermore Supply Improvements project, was renamed the Lawrence Livermore Water Quality Improvements Project. Therefore, the SJRWQIP EIR describes and evaluates two projects: The Tesla Treatment Facility (at the Tesla Portal site) and the Lawrence Livermore Water Quality Improvements (at the Thomas Shaft site). For purposes of the EIR, these projects were evaluated as one project given their geographic proximity, construction schedule, and the interrelated function of the two proposed facilities at the Tesla Portal site.

Funding for the project is included in the WSIP supplemental appropriation request recently presented to the Board of Supervisors in December 2008.

APPROVAL:

PERFORMING ORGANISATION		FINANCE	Todd Rydstrom
COMMISSION SECRETARY	Michael Housh	GENERAL MANAGER	Ed Harrington

Tesla Treatment Facility (Tesla Portal Site)

At the Tesla Portal site, new water treatment facilities would be constructed to meet U.S. Environmental Protection Agency (U.S. EPA) requirements for *Cryptosporidium* reduction/inactivation in drinking water, as required under the U.S. EPA's Long Term-2 Enhanced Surface Water Treatment Rule (LT2ESWTR). The existing building that contains the Tesla Portal Hypochlorite Station would be replaced with a new Chemical Process Building and Office/Control Building. An ultraviolet (UV) facility would be constructed, which would disinfect water using a series of UV light arrays. The project components include:

- A 14,000-square-foot Chemical Process Building 32 feet in height containing three 16,000-gallon sodium hypochlorite tanks, two 10,000-gallon fluoride tanks and two outdoor 12,500-gallon carbon dioxide (CO2) tanks
- A 3,500-square-foot Office/Control Building 12 feet in height containing offices, control room, process room, laboratory, restrooms, lockers, shower, and a multipurpose room
- A 20,000-square-foot UV Building 32 feet in height containing 12 UV reactors (10 active and two standby) each with UV lamp arrays and various sensors, on a floor recessed approximately 14 feet below grade, below-grade piping vaults and two 3,000-gallon food-grade acid tanks
- Other proposed improvements at the Tesla Portal site include a 90,000-gallon containment basin lined with rip rap to capture released water for grit removal and periodic maintenance (three times per month), two valve vaults to direct adequate flow, as required, two valve houses, and other infrastructure including a microwave tower up to 100 feet in height

Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)

At the Thomas Shaft site, the Lawrence Livermore Water Quality Improvements would upgrade existing water treatment with a UV facility to meet disinfection requirements of the Surface Water Treatment Rule (SWTR) and the LT2ESWTR. The project includes:

- Two UV reactors (one active and one standby) installed within the existing Chlorination Facility building
- A 360-square-foot prefabricated structure 10 feet in height within the fenced area atop Thomas Shaft

- A 2,500-gallon percolation water tank for process water

The Lawrence Livermore Water Quality Improvements are being designed for a 0.165 million gallons per day (mgd) capacity. The proposed project would allow Lawrence Livermore National Laboratory (LLNL) to take up to 0.165 mgd of their annual average demand of 0.8 mgd from Thomas Shaft, and continue to receive the remainder of the water from Mocho Shaft, a SFPUC facility located downstream of the Thomas Shaft site. The amount of water supplied to LLNL would be consistent with the existing contract between the two parties.

Adoption of CEQA Findings

The City Planning Department prepared and the Planning Commission will be asked to certify on December 18, 2008, an EIR for the SJRWQIP as required under CEQA, the CEQA Guidelines and Chapter 31 of the San Francisco Administrative Code. In order to comply with CEQA requirements, as part of the approval of the Tesla Treatment Facility and Lawrence Livermore Water Quality Improvements projects, the Commission must adopt the CEQA Findings, including a Statement of Overriding Considerations, and the MMRP, attached to the Resolution as Attachments A and B, respectively.

The SJRWQIP Final EIR (consisting of the Draft EIR and the Comments and Responses document) assessed the projects and identified some potentially significant adverse impacts to the environment, primarily related to biological resources, which can be mitigated to less than significant levels. These impacts will be reduced to less than significant levels by incorporating the mitigation measures outlined in the EIR and the MMRP in the project final design and incorporating them in the construction phase. All Project-specific significant impacts will be mitigated to a less-than-significant level. The CEQA Findings provide for adoption of the mitigation measures by the SFPUC and the MMRP provides information and allocates responsibility for implementing all of the mitigation measures proposed in the Final EIR for the SJRWQIP.

The SJRWQIP is part of the WSIP, and implementation of the WSIP would support growth in the SFPUC service area, thereby contributing indirectly to environmental impacts caused by that growth. Because the proposed projects are part of the WSIP and would contribute to the WSIP's growth inducement impact, the projects therefore would contribute to the significant and unavoidable program-level impacts associated with growth inducement. The WSIP water supply decision also caused other significant and unavoidable impacts. Because this Project is part of the WSIP, it is deemed to contribute to those impacts.

Significant and unavoidable impacts associated with the WSIP are described in Section IV of the CEQA Findings attached to the Commission Resolution as Attachment A. Therefore, this Commission will need to adopt a Statement of

Overriding Considerations, included in the CEQA Findings Section VI, explaining why the Commission has decided to approve the Tesla Treatment Facility and Lawrence Livermore Water Quality Improvements projects notwithstanding this significant and unavoidable environmental impact.

RECOMMENDATION

SFPUC staff recommends that the Commission **approve** the Tesla Treatment Facility and the Lawrence Livermore Water Quality Improvements Projects; **adopt** the CEQA Findings, including the statement of overriding considerations, and the MMRP and **authorize** staff to implement the projects following final action by the Board of Supervisors.

CONTEXT OF THIS ACTION

The WSIP is a multi-billion dollar multi-year program to upgrade the SFPUC's drinking water system. The program will deliver capital improvements that enhance the SFPUC's ability to provide reliable, affordable, high quality drinking water to its 27 wholesale customers and regional retails customers in Alameda, Santa Clara and San Mateo Counties, and to 800,000 retail customers in the City and County of San Francisco, in an environmentally sustainable manner. The proposed WSIP is structured to cost-effectively meet water quality requirements, improve seismic and delivery reliability, and meet water supply reliability goals.

The overall objectives of the SJRWQIP are to meet current and foreseeable future federal and state water quality requirements and to reduce the vulnerability of the regional water system to damage in the event of a major earthquake. The objectives are consistent with the project-specific objectives described in the WSIP PEIR. Specific project objectives are to:

Tesla Treatment Facility (Tesla Portal Site)

- Replace existing water treatment facilities that are not currently seismically safe with new facilities that are designed to meet current seismic, safety/fire, and building code standards

- Construct new water treatment facilities to meet U.S. EPA requirements for *Cryptosporidium* reduction/inactivation in drinking water, as required under the U.S. EPA's LT2ESWTR

- Improve current water quality management capabilities such as pH control

Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)

- Construct new water treatment facilities to meet U.S. EPA requirements under the SWTR for the reduction/inactivation of *Giardia*, as well as assist in meeting LT2ESWTR *Cryptosporidium* requirements to enable delivery of potable water to LLNL from the Thomas Shaft of the Coast Range Tunnel

- Continue to provide back-up chlorination capabilities

The SJRWQIP Draft EIR was completed and made available to local regulatory agencies (Responsible Agencies) and the general public on August 25, 2008. The 45-day public review period ended on October 8, 2008. Public comments on the DEIR were received between August 25, 2008 and October 8, 2008. A total of nine (9) written public comments were received during the public comment period. These letters were from the California Department of Transportation (Caltrans), California Department of Fish and Game (CDFG), California Governor's Office of Planning and Research (OPR), San Francisco Department of Public Health, San Francisco Landmarks Preservation Advisory Board, Bay Area Water Supply and Conservation Agency (BAWSCA), San Joaquin Valley Air Pollution Control District (SJVAPCD), Steve Lawrence, and the Plasterers' and Cement Masons' Local Union. In addition two speakers provided oral comments at the public hearing in Tracy, California and no comments were received at the public hearing in San Francisco, California. All comments received were carefully considered, responded to, and revisions were made to the DEIR in response to these comments.

This request to approve the Tesla Treatment Facility and Lawrence Livermore Water Quality Improvements projects will allow the SFPUC to proceed with current plans to advertise a construction contract for CUW36401 Lawrence Livermore Water Quality Improvement Project, issue Notice To Proceed (NTP) for Phase 2A – Final Design, Long Lead Item Procurement and Fabrication of Material for Contract DB116, Tesla Treatment Facility, and proceed with the project improvements.

PROS/CONS

PROS

- SFPUC will proceed with meeting the objectives of the Tesla Treatment Facility and Lawrence Livermore Water Quality Improvement Projects.
- SFPUC will proceed with the improvements needed to meet U.S. EPA requirements for *Cryptosporidium* reduction/inactivation in drinking water, as required under the U.S. EPA's LT2ESWTR.

- SFPUC will proceed with meeting U.S. EPA requirements under the SWTR for the reduction/inactivation of *Giardia* to meet our contractual obligations to deliver potable water to LLNL from the Thomas Shaft of the Coast Range Tunnel.

CONS

- SFPUC will not be able to proceed with plans to meet our mandatory compliance deadline for the U.S. EPA requirements under the LT2ESWTR.
- SFPUC will not be able to meet our contractual obligations to deliver potable water to LLNL from the Thomas Shaft.
- SFPUC will not be able to replace facilities at the Tesla Portal site to reduce the vulnerability of the system to earthquakes and other seismic hazards.

PUBLIC UTILITIES COMMISSION

City and County of San Francisco

RESOLUTION NO. **08-0234**

WHEREAS, Public Utilities Commission staff have developed a project description under the Water System Improvement Program (WSIP) for the improvements to the regional water supply system, otherwise known as Project No. CUW38401, Tesla Treatment Facility and Project No. CUW36401 Lawrence Livermore Water Quality Improvements; and

WHEREAS, the objectives of the Project are to meet current and foreseeable future federal and state water quality requirements and reduce the vulnerability of the system to earthquakes and other seismic hazards; and

WHEREAS, a Draft Environmental Impact Report (DEIR) for the Project was prepared and published for public review on August 25, 2008; and

WHEREAS, public comments on the Draft EIR were received between August 25, 2008 and October 8, 2008; and

WHEREAS, on December 18, 2008, the Planning Commission reviewed and considered the Final EIR in Planning Department File No. 2007052109, consisting of the Draft EIR and the Comments and Responses document, and found that the contents of said report and the procedures through which the Final EIR was prepared, publicized and reviewed complied with the provisions of the California Environmental Quality Act (CEQA), the CEQA Guidelines and Chapter 31 of the San Francisco Administrative Code ("Chapter 31") and found further that the Final EIR reflects the independent judgment and analysis of the City and County of San Francisco, is adequate, accurate and objective, and that the Comments and Responses document contains no significant revisions to the Draft EIR, and certified the completion of said Final EIR in compliance with CEQA, the CEQA Guidelines and Chapter 31 in its Motion No. 17784; and

WHEREAS, this Commission has reviewed and considered the information contained in the Final EIR, all written and oral information provided by the Planning Department, the public, relevant public agencies, SFPUC and other experts and the administrative files for the WSIP and the EIR; and

WHEREAS, the EIR files have been made available for review by the Public Utilities Commission and the public, and those files are part of the record before this Public Utilities Commission; and

WHEREAS, Public Utilities Commission staff prepared Findings, as required by CEQA, and a Mitigation, Monitoring and Reporting Program (MMRP), which material was made available to the public and the Commission for the Commission's review, consideration and action; now, therefore, be it

RESOLVED, that the Public Utilities Commission has reviewed and considered the EIR and the record as a whole and hereby adopts the CEQA Findings, including the Statement of Overriding Considerations, attached to this Resolution as Attachment A and incorporated herein as part of this Resolution by this reference thereto, and adopts the Mitigation Monitoring and Reporting Program attached to this Resolution as Attachment B and incorporated herein as part of this Resolution by this reference thereto, and authorizes a request to the Board of Supervisors to adopt the same CEQA Findings, Statement and MMRP; and, be it

of this Resolution by this reference thereto, and authorizes a request to the Board of Supervisors to adopt the same CEQA Findings, Statement and MMRP; and, be it

FURTHER RESOLVED, that the Public Utilities Commission hereby adopts the SFPUC Standard Construction Measures and Greenhouse Gas Reduction Actions attached hereto as Attachment C; and, be it

FURTHER RESOLVED, that the Public Utilities Commission hereby approves WSIP-funded Project No. CUW38401, Tesla Treatment Facility and WSIP-funded Project No. CUW36401 Lawrence Livermore Water Quality Improvements; and authorizes staff to issue a Notice to Proceed (NTP) for Phase 2A – Final Design, Long Lead Item Procurement and Fabrication of Material for Contract DB116 Tesla Treatment Facility, and to advertise a construction contract for Lawrence Livermore Water Quality Improvements.

I hereby certify that the foregoing resolution was adopted by the Public Utilities Commission at its meeting of December 18, 2008

CHAPTER 1
Executive Summary

1.1 Introduction and Purpose

The San Francisco Public Utilities Commission (SFPUC) proposes to construct the *San Joaquin Regional Water Quality Improvement Project* (project). The proposed project is located in unincorporated San Joaquin County at two existing facility sites, the Tesla Portal site and the Thomas Shaft site, along the SFPUC's regional water system. At the Tesla Portal site, the existing building that contains the Tesla Portal Hypochlorite Station would be replaced with a new Chemical Process Building and Office/Control Building. An ultraviolet (UV) facility would be constructed, which would disinfect water using a series of UV light arrays. At the Thomas Shaft site, the Lawrence Livermore Water Quality Improvements would upgrade existing water treatment with a UV facility to meet disinfection requirements of the Surface Water Treatment Rule and the Long Term 2 Enhanced Surface Water Treatment Rule.

The San Francisco Planning Department, Major Environmental Analysis (MEA) Section, determined that implementation of the proposed project could have a significant effect on the environment and, therefore, requires preparation of an Environmental Impact Report (EIR) pursuant to the requirements of the California Environmental Quality Act (CEQA). This EIR is intended to provide the public and responsible agencies with information about the potentially significant environmental effects of the proposed project, to identify possible ways to minimize the potentially significant effects, and to describe and evaluate feasible alternatives to the proposed project.

1.2 Project Description and Objectives

The proposed *San Joaquin Regional Water Quality Improvement Project* would consist of the following components. These, and other secondary components of the proposed project, are described in detail in Chapter 3, Project Description.

1.2.1 Tesla Treatment Facility (Tesla Portal Site)

- A 14,000-square-foot Chemical Process Building 32 feet in height containing three 16,000-gallon sodium hypochlorite tanks, two 10,000-gallon fluoride tanks and two outdoor 12,500-gallon carbon dioxide (CO_2) tanks

- A 3,500-square-foot Office/Control Building 12 feet in height containing offices, control room, process room, laboratory, restrooms, lockers, shower, and a multipurpose room

- A 20,000-square-foot UV Building 32 feet in height containing 12 UV reactors (10 active and two standby) each with UV lamp arrays and various sensors, on a floor recessed approximately 14 feet below grade, below-grade piping vaults and two 3,000-gallon food-grade acid tanks

- Other proposed improvements at the Tesla Portal site include a 90,000-gallon containment basin lined with rip rap to capture released water for grit removal and periodic maintenance (three times per month), two valve vaults to direct adequate flow, as required, two valve houses, and other infrastructure including a microwave tower up to 100 feet in height

1.2.2 Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)

- Two UV reactors (one active and one standby) installed within the existing Chlorination Facility building

- A 360-square-foot prefabricated structure 10 feet in height within the fenced area atop Thomas Shaft

- A 2,500-gallon percolation water tank for process water

The proposed project would improve already-existing uses (i.e., water treatment) at the two sites. The Lawrence Livermore Water Quality Improvements are being designed for a 0.165 million gallons per day (mgd) capacity. The proposed project would allow Lawrence Livermore National Laboratory (LLNL) to take up to 0.165 mgd of their annual average demand of 0.8 mgd from Thomas Shaft, and continue to receive the remainder of the water from Mocho Shaft, an SFPUC facility located downstream of the Thomas Shaft site. The amount of water supplied to LLNL would be consistent with the preexisting contract between the two parties.

1.2.3 Project Objectives

The objectives of the proposed *San Joaquin Regional Water Quality Improvement Project* (project) consist of the following:

Tesla Treatment Facility (Tesla Portal Site)

- Replace existing water treatment facilities that are not currently seismically safe with new facilities that are designed to meet current seismic, safety/fire, and building code standards

- Construct new water treatment facilities to meet U.S. Environmental Protection Agency (U.S. EPA) requirements for *Cryptosporidium* reduction/inactivation in drinking water, as required under the U.S. EPA's Long Term-2 Enhanced Surface Water Treatment Rule (LT2ESWTR)

- Improve current water quality management capabilities such as pH control

Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)

- Construct new water treatment facilities to meet U.S. EPA requirements under the Surface Water Treatment Rule (SWTR) for the reduction/inactivation of *Giardia*, as well as assist in meeting LT2ESWTR *Cryptosporidium* requirements to enable delivery of potable water to LLNL from the Thomas Shaft of the Coast Range Tunnel

- Continue to provide back-up chlorination capabilities

1.2.4 Standard Construction Measures

The SFPUC has adopted standard construction measures that would be implemented as part of all SFPUC projects, including the proposed project. The main objective of these measures is to minimize potential disruption of surrounding neighborhoods during construction and to reduce impacts on environmental resources to the extent feasible. The construction measures would be implemented individually for the facility improvements; some measures might not be applicable to some projects, while some projects would require the development of more detailed construction measures and implementation steps as the individual projects are designed. The standard construction measures to be included in project construction contracts address the following topics: neighborhood notice, seismic and geotechnical studies, onsite air and water quality measures during construction, groundwater, traffic, noise, hazardous materials, biological resources, cultural resources, and project site (i.e., the use of non-City and County of San Francisco [CCSF]-owned land during construction, which is not proposed for this project). The entire list of measures is presented in Chapter 3.

1.2.5 Proposed Construction Schedule

Construction of the Tesla Treatment Facility is anticipated to start in January 2009, and last approximately 24 months. After construction, there would be a 12-month startup testing period including UV tests by State regulators.

Construction of the Lawrence Livermore Water Quality Improvements is anticipated to start in July 2009, and last for approximately six months.

Construction at both sites generally would be conducted on weekdays from 7:00 am to 5:00 pm; however, work may occur occasionally on weekends, and could occur 24 hours a day, seven days a week at the Tesla Portal site during tie-in of the new facilities during the regularly scheduled Hetch Hetchy shutdown for approximately 36 days in January to February.

1.3 Summary of Environmental Impacts and Mitigation

Chapter 4 of this EIR evaluates the environmental effects of implementing the proposed project. Chapter 5 presents mitigation measures that would reduce potentially significant impacts to less-than-significant levels, when feasible. A summary of significant impacts and mitigation measures is provided in Table 1-1 at the end of this chapter.

- As discussed in Chapter 6, Growth Inducement, the proposed project is one of several improvement projects that comprise the SFPUC's Water System Improvement Program (known as the "Phased WSIP Variant"), and implementation of the WSIP would support growth in the SFPUC service area, thereby contributing indirectly, to environmental impacts caused by that growth. Because the proposed project is part of the WSIP and would contribute to the WSIP's growth inducement impact, the project therefore would contribute to the potentially significant and unavoidable program-level impacts associated with growth inducement.

1.4 Areas of Controversy

No areas of controversy were raised by the public or responsible agencies during the 30-day Notice of Preparation (NOP) review period, which extended from May 16 through June 18, 2007, nor have any become known to the San Francisco Planning Department since that time.

1.5 Alternatives to the Proposed Project

CEQA requires that EIRs describe and evaluate the comparative merits of a range of reasonable alternatives to projects, or to project locations, which would: (1) feasibly attain most of the basic project objectives; and (2) would avoid or substantially lessen any of the projects' significant effects. In addition to the CEQA required No Project Alternative, the alternatives described below are evaluated in Chapter 9, CEQA Alternatives, of this EIR. The Environmentally Superior Alternative is also discussed in Chapter 9.

1.5.1 Continue Water Source to Artificial Wetland at Tesla Portal Site

Under this alternative, the SFPUC would continue to provide a year round water source to the artificial wetland area at the Tesla Portal site. The source of water would change, from existing analyzer equipment to the new analyzer equipment to be located adjacent to the artificial wetland area. The amount of water provided would be roughly the same quantity that currently feeds the wetland area. Under this alternative, all other aspects of the proposed project would be implemented as described in Chapter 3. This alternative would meet the project objectives.

1.5.2 Combine Office/Control Building and UV Building at Tesla Portal Site

This alternative proposes to combine the 3,500-square-foot Office/Control Building and the UV Building in a single, two-story structure at the Tesla Portal site. Under this alternative, the total building footprint would be smaller than the proposed project; however, a two-story structure would be built instead of only one-story structures. All other improvements at the Tesla Portal site as well as the Lawrence Livermore Water Quality Improvements would be implemented as described in Chapter 3. This alternative would meet the project objectives.

1.5.3 Retrofit of Existing Tesla Portal Hypochlorite Station Building

Under this alternative, the SFPUC would retrofit the existing building that contains the Tesla Portal Hypochlorite Station rather than construct a new Chemical Process Building. This alternative would reduce the total building footprint at the Tesla Portal site. The Tesla Portal

facility must be capable of providing disinfection during the retrofit of the building. Consequently, a temporary chemical feed facility would be constructed southeast of the existing building. The Thomas Shaft Chlorination Facility would continue to provide backup disinfection.

All other improvements at the Tesla Portal site as well as the Lawrence Livermore Water Quality Improvements would be implemented as described in Chapter 3.

This alternative would not accommodate the pH adjustment equipment and, therefore, that project objective would not be met, and a building for this equipment may be needed in the future.

1.6 Overview of SFPUC Regional Water System

The proposed project is a component of the SFPUC's WSIP. As a component of the WSIP, it contributes to the impacts that the WSIP, as a program, may have on the environment. To address the potential environmental impacts of the proposed WSIP, the San Francisco Planning Department prepared a Program EIR (PEIR) that was certified by the San Francisco Planning Commission on October 30, 2008 (Motion No. 17734). At a project-level of detail, the PEIR evaluated the environmental impacts of the WSIP and, at a program-level of detail, it evaluated the environmental impacts of the WSIP's facility improvement projects. This section provides background on the SFPUC's water system, and the following sections provide background on the WSIP and the PEIR.

The CCSF, through the SFPUC, owns and operates a regional water system that extends from the Sierra Nevada to San Francisco and serves retail and wholesale customers in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne counties. The regional water system consists of water conveyance, treatment, and distribution facilities, and delivers water to retail and wholesale customers. The existing regional system includes over 280 miles of pipelines, over 60 miles of tunnels, 11 reservoirs, five pump stations, and two water treatment plants. The SFPUC currently delivers an annual average of about 265 mgd of water to its customers. The source of the water supply is a combination of local supplies from streamflow and runoff in the Alameda Creek watershed and in the San Mateo and Pilarcitos Creeks watersheds (referred to together as the Peninsula watersheds), augmented with imported supplies from the Tuolumne River watershed. Local watersheds provide about 15 percent of total supplies and the Tuolumne River provides the remaining 85 percent.

The SFPUC serves about one-third of its water supplies directly to retail customers, primarily in San Francisco, and about two-thirds of its water supplies to wholesale customers by contractual agreement. The wholesale customers are largely represented by the Bay Area Water Supply and Conservation Agency, which consists of 27 total customers. Some of these wholesale customers have other sources of water in addition to what they receive from the SFPUC regional system, while others rely completely on the SFPUC for supply.

1.6.1 SFPUC Water System Improvement Program

On October 30, 2008, the SFPUC adopted a regional WSIP (known as the "Phased WSIP Variant") (refer to www.sfwater.org; SFPUC, 2008e). The WSIP would improve the regional

system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area through the year 2018 and would establish level of service goals and system performance

objectives. The proposed program area spans seven counties—Tuolumne, Stanislaus, San Joaquin, Alameda, Santa Clara, San Mateo, and San Francisco.

- The WSIP includes a water supply strategy and modifications to system operations, and construction of a series of facility improvement projects. The proposed project, along with several other facility improvement projects, is a component of the WSIP.[1] The overall goals of the WSIP are to maintain high-quality water; reduce vulnerability to earthquakes; increase delivery reliability and improve the ability to maintain the system; meet customer water supply needs; enhance sustainability in all system activities; and achieve a cost-effective, fully operational system (refer to Table 2-1, WSIP Goals and Objectives). To further these program goals, the WSIP also includes objectives that address system performance in the areas of water quality, seismic reliability, delivery reliability, and water supply through the year 2018. (See SFPUC Resolution No. 08-0200.)

- To address the potential environmental impacts of the WSIP, the San Francisco Planning Department prepared a PEIR, which was certified by the San Francisco Planning Commission on October 30, 2008 (San Francisco Planning Commission Motion No. 17734). At a project-level of detail, the PEIR evaluated the environmental impacts of the WSIP's water supply strategy and, at a program level of detail, it evaluated the environmental impacts of the WSIP's facility improvement projects. The following sections summarize the WSIP and system operation strategy, along with WSIP's impacts and mitigation measures, as identified in the PEIR.

Program Description

- The WSIP involves phased implementation of a water supply strategy to meet projected water demand through 2018. It also includes full implementation of all proposed WSIP facility improvement projects to insure that the public health, seismic safety and delivery reliability goals are achieved as soon as possible.[2] Under the WSIP, the SFPUC established an interim mid-term planning horizon – 2018. Thus, the SFPUC made a decision about providing water supply to its customers through 2018 only, and is deferring a decision regarding long-term water supply after 2018 and through 2030 until it undertakes further water supply planning and demand analysis.

- The WSIP includes the following key program elements:

- Full implementation of all of the 17 proposed WSIP facility improvement projects described in the PEIR.

- Water supply delivery to regional water system customers through 2018 only of 265 mgd average annual target delivery originating from the Tuolumne, Alameda and Peninsula

[1] The proposed project is listed as three separate projects in the WSIP PEIR: the Tesla Portal Disinfection Facility, the Hetch Hetchy Advanced Disinfection, and the Lawrence Livermore Supply Improvements. For purposes of this EIR, these three projects are evaluated as one project given their geographic proximity, construction schedule, and the interrelated function of the two proposed facilities at the Tesla Portal site.

[2] The size and design of the WSIP facility improvement projects are driven by the SFPUC's system performance objectives and would not change as a result of the water supply decision included as part of the WSIP. (SFPUC Resolution No. 08-0200.)

watersheds. This includes 184 mgd for the wholesale customers (including 9 mgd for the cities of San Jose and Santa Clara), and 81 mgd for the retail customers.

- Development of 20 mgd of conservation, recycled water and groundwater within the SFPUC service area (10 mgd in the retail service area and 10 mgd wholesale service area).

- Dry year transfer from Modesto and/or Turlock Irrigation Districts of about 2 mgd coupled with the Westside Groundwater Basin conjunctive-use project to meet the drought year goal of limiting rationing to no more than 20 percent on a systemwide basis.

- Re-evaluation of 2030 demand projections, potential regional water system purchase requests, and water supply options by 2018 and a separate SFPUC decision in 2018 regarding regional water system water deliveries after 2018.

- Financial incentives to limit water sales to an annual average of 265 mgd from the watersheds.

- The WSIP would not provide water supply to meet 300 mgd average annual customer purchase requests in 2030 as proposed under the original WSIP. Rather, under the WSIP, the SFPUC will deliver to customers up to 265 mgd from the SFPUC watersheds on an average annual basis. While average annual deliveries from the SFPUC watersheds would be limited to 265 mgd, such that there would be no increase in diversions from the Tuolumne River to serve additional demand, there would be a small increase in average annual Tuolumne River diversions of about 2 mgd over existing conditions in order to meet delivery and drought reliability goals through 2018.

- The SFPUC must maintain water deliveries to all its customers for the protection of public health and safety. Therefore, the SFPUC will work with its customers to develop financial incentives to limit water sales to an average annual amount of 265 mgd from the watersheds through 2018. With the projected 20 mgd of conservation, recycled water, and groundwater projects, the system would meet average daily demand of 285 mgd in 2018.

WSIP System Operation Strategy

The WSIP also provides a future operating strategy for the regional water system, which addresses the condition of the physical facilities and infrastructure while accounting for factors that affect the system including fluctuating customer demand, meteorological and hydrological conditions, facility and infrastructure capacity and maintenance requirements, and institutional parameters. The operating strategy addresses four components of system operation: water supply and storage, water quality, water delivery, and asset management.

Day-to-day operation of the regional water system under the WSIP would be similar to existing operations, but would provide for additional facility maintenance activities and improved emergency preparedness. This would allow the SFPUC to meet its WSIP objectives and provide for increased system reliability and additional flexibility for scheduling repairs and maintenance. The proposed operations strategy would also include a multistage drought response program. Under the WSIP, regional water system operations would continue to comply with all applicable institutional and planning requirements including complying with all water quality, environmental, and public safety regulations; maximizing the use of water from local watersheds; assigning a higher priority to water delivery over hydropower generation; and meeting all downstream flow requirements.

- ## Summary of Water Supply/Operations Impacts

- The PEIR analyzed potential water supply and system operations impacts within the following geographic regions: the Tuolumne River, Alameda Creek, Peninsula, and Westside Basin groundwater resources systems. The PEIR also identified the cumulative effects of implementing the WSIP and system operations in combination with other past, present, and reasonably foreseeable future projects within each of these watersheds. It also discussed the potential effects of climate change and global warming on the regional water system.

- The WSIP would result in changes in reservoir levels and associated changes in downstream flows in rivers and creeks in the three affected watersheds, potentially resulting in groundwater, water quality, fisheries, and terrestrial biological resource impacts. In the event that deliveries to customers exceed 265 mgd, streamflow changes in the Tuolumne River watershed could affect fisheries and terrestrial biological resources. In the Alameda Creek and Peninsula watersheds, the WSIP, which includes restoring the historical storage capacities of Calaveras and Lower Crystal Springs Reservoirs, could affect reservoir levels, downstream flows, fisheries, and terrestrial biological resources. In addition, similar to the originally proposed WSIP, the WSIP will develop groundwater supplies in the North Westside Groundwater Basin as well as a conjunctive-use program in the South Westside Groundwater Basin.

The following list summarizes the WSIP impacts identified in the PEIR that are potentially significant but mitigable; potentially significant and unavoidable; and significant and unavoidable. As set forth in the PEIR, the San Francisco Planning Department has determined the potential environmental impacts on all resources not listed below would be less than significant and no mitigation measures would be required. (Refer to Chapter 6 and Appendix B.1 for further discussion of the WSIP water supply impact analysis).

Potentially Significant But Mitigable WSIP Water Supply Impacts

- Fisheries Resources: Tuolumne River; (below La Grange Dam, only when average annual deliveries from the watersheds exceed 265 mgd); Alameda Creek
- Terrestrial Biological Resources: Tuolumne River (below La Grange Dam, only when average annual deliveries from the watersheds exceed 265 mgd; and impacts on alluvial features that support meadow and riparian habitat from O'Shaughnessy Dam to Don Pedro Reservoir); Calaveras Reservoir; Alameda Creek; Calaveras Creek; Upper and Lower Crystal Springs Reservoir
- Groundwater: Pumping overdraft; change in water levels in Lake Merced and other surface water features; seawater intrusion due to decreased groundwater levels; contamination of drinking water

Potentially Significant and Unavoidable WSIP Water Supply Impacts

- Fisheries: Upper and Lower Crystal Springs Reservoir
- Growth Inducement: SFPUC Service Area

Significant and Unavoidable WSIP Water Supply Impacts

- Streamflow: Alameda Creek below Alameda Creek Diversion Dam

Alternatives to the WSIP

The PEIR evaluated seven alternatives to the WSIP, listed below, because of their apparent ability to meet most of the WSIP's goals, their ability to reduce one or more of the potentially significant impacts associated with program implementation, their potential feasibility, and their collective ability to provide a reasonable range of alternatives to foster informed decision-making and public participation. Analysis of the No Program Alternative is included as required by CEQA. Section 9.2 in the Alternatives chapter and Appendix B.3 present a more detailed summary of these alternatives.

- No Program Alternative: The SFPUC would implement only those facility improvement projects driven by regulatory requirements or existing agreements with regulatory agencies.
- No Purchase Request Increase Alternative: The SFPUC would serve wholesale customers only the amount of water required under the existing Master Water Sales Agreement between CCSF and each of the wholesale customers.

- Aggressive Conservation/Water Recycling and Local Groundwater Alternative: The SFPUC would implement all of the proposed WSIP projects, but would endeavor to accommodate increased customer purchase requests only through additional conservation, water recycling, and local groundwater projects.

- Lower Tuolumne River Diversion Alternative: The SFPUC would implement all of the proposed WSIP projects, but would serve the projected increase in customer purchase requests through 2030 through diversions from the lower Tuolumne River.

- Year-round Desalination at Oceanside Alternative: The SFPUC would implement all of the proposed WSIP projects and would construct a 25-mgd desalination plant in San Francisco to serve the projected increase in customer purchase requests through 2030.

- Regional Desalination for Drought Alternative: The SFPUC would implement all of the proposed WSIP projects and would partner with other Bay Area water agencies to construct and operate a regional desalination plant that would provide the SFPUC with supplemental supply during drought years.

- Modified WSIP Alternative: The SFPUC would implement all of the proposed WSIP projects, but would modify proposed system operations to minimize environmental effects.

- The adopted WSIP (see SFPUC Resolution No. 08-0200) incorporates elements of three alternatives: the No Purchase Request Alternative, the Aggressive Conservation/Water Recycling and Groundwater Alternative, and the Modified WSIP Alternative.

- CEQA also requires the identification of an environmentally superior alternative from among the proposed project and the set of alternatives evaluated. The Draft PEIR identified the Modified WSIP Alternative as the environmentally superior alternative for the 2030 planning horizon because it would reduce key impacts of the originally proposed WSIP on natural resources along the lower Tuolumne River, in Alameda and Pilarcitos Creeks, and in/around Crystal Springs and Pilarcitos Reservoirs, but it would continue to meet the WSIP's primary goals and objectives. Like the adopted WSIP (known as the "Phased WSIP Variant" in the Final PEIR), the Modified WSIP Alternative would maximize the use of existing facilities and the largely gravity-driven system without also requiring the construction of additional major facilities called for under many other alternatives, or substantially increasing the energy demand of the system or need for pumping. The Modified WSIP Alternative would have more impacts on the upper Tuolumne River, and possibly less on the Lower Tuolumne River. The adopted WSIP is substantially similar to the Modified WSIP Alternative in that it includes essentially the same elements through 2018.

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
Land Use and Visual Quality			
Impact 4.3-5: Permanent adverse impacts on scenic vistas or scenic resources	Tesla Portal: PSM Thomas Shaft: N/A	Mitigation Measure 4.3-5a – Architectural Design: The design of the proposed buildings at the Tesla Treatment Facility shall consider the existing visual character of the site and surrounding area, including the visibility of facilities and related structures from I-580. Proposed buildings shall be designed to minimize the intrusion of structures into the natural setting of the site by using colors that are compatible with the existing architecture and visual character of the site.	Tesla Portal
		Mitigation Measure 4.3-5b – Landscape Screens: In addition to revegetation of disturbed areas per SFPUC Standard Construction Measure #10 and Mitigation Measure 4.6-2, new plantings and/or a landscape berm shall be required to screen views of new structures and equipment from I-580 (a designated state scenic highway) to the extent possible, provided that such landscaping does not affect security of SFPUC facilities.	Tesla Portal
Geology and Soils			
Impact 4.4-9: Expansive or corrosive soils	Tesla Portal: PSM Thomas Shaft: PSM	Mitigation Measure 4.4-9 – Characterize Extent of Expansive and Corrosive Soil: If the screening analysis conducted in accordance with SFPUC Standard Construction Measure #2 identifies a potential for expansive or corrosive soils, the site-specific geotechnical investigation shall include a characterization of the presence and extent of expansive and corrosive soil at the project sites. The results and recommendations of the investigation shall be incorporated into the final project design for the Tesla Treatment Facility. For the Lawrence Livermore Water Quality Improvements, prior to construction, the SFPUC shall obtain soil samples for testing of corrosive/expansive soils and use to adjust the final project design of the pipeline, or, alternatively, the SFPUC shall implement a conservative design approach of the pipeline which shall address potential corrosivity.	Tesla Portal and Thomas Shaft
Biological Resources			
Impact 4.6-1: Impacts on wetlands and aquatic resources (construction-related impacts) and Impact 4.6 4: Impacts on	Tesla Portal: PSM Thomas Shaft: N/A	Mitigation Measure 4.6-1a – Participate in the SJMSCP: Prior to the commencement of construction activities, SFPUC shall coordinate with the Joint Powers Authority (JPA)/ Technical Advisory Committee (TAC), implement relevant ITMMs for applicable species (as identified in Mitigation Measures 4.6-3b through 4.6-3l) and pay any necessary fees to fund offsite compensation under the terms of the SJMSCP to provide replacement values	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
wetlands and aquatic resources (operational impacts)		that are equal to that of the permanent loss of 3.2 acres of California annual grasslands and 0.01 acre of ruderal/disturbed land, and temporary impacts to 11.72 acres of California annual grassland and 0.96 acre of ruderal/disturbed land, and incidental take authorization for special-status species. Mitigation Measure 4.6-1b – Implement Best Management Practices to Protect the Artificial Wetland and Ephemeral Drainage: SFPUC shall implement Best Management Practices to ensure that natural flow is maintained in the ephemeral drainage during and after construction of the pipeline at the ephemeral drainage. Natural flow will be maintained by restricting construction to the dry season (e.g., April 15 – October 15) or by diverting water around the construction area (e.g., a dam and a pump) or through the construction area (e.g., a culvert) in the ephemeral drainage during the wet season (e.g., October 16 – April 14). The drainage channel will be restored and recontoured to pre-existing conditions after construction. In addition, prior to the start of staging, ground disturbing activities, or large-scale materials off-haul or delivery, SFPUC shall require the contractor to implement the following actions intended to avoid or reduce indirect and direct impacts on the ephemeral drainage at the Tesla Portal site. • SFPUC or its contractor(s) shall install appropriate erosion control (e.g., certified weed free straw bales, silt fencing, straw wattles, erosion and sediment control fabric) at the pipeline crossing and the intersections of the road and the ephemeral drainage to minimize potential for increased sedimentation and turbidity. • SFPUC shall prohibit its contractor(s) from refueling, washing, and repairing equipment in and near (i.e., within at least 25 feet) the ephemeral drainage at the Tesla Portal project site. • SFPUC shall require fencing of the artificial wetland and ephemeral drainage (e.g., temporary construction "orange mesh" fencing or silt fencing) adjacent to the footprint of the pipeline crossing and the access road crossing, and shall require signage to be placed at the sites indicating that it is a restricted area. SFPUC shall require its contractor(s) to stay out of the fenced and signed area. SFPUC shall require its	Tesla Portal

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		contractor(s) to limit vehicle speeds to 15 mph on unpaved roads in the vicinity of the fenced areas of the artificial wetland and ephemeral drainage to prevent dust effects. SFPUC shall also require its contractor(s) to control dust (i.e., stabilization of dust emissions using water or chemical stabilizer/suppressant) along the existing access road leading to the Tesla Portal project site (including the area at the intersection with the artificial wetland), as required to control dust (refer also to Mitigation Measure 4.9-1a, SJVAPCD Dust Control Measures).	
Impact 4.6-2: Impacts to sensitive habitats, common habitats, and heritage trees	Tesla Portal: PSM Thomas Shaft: LS	Mitigation Measure 4.6-2 – Return Site to Pre-Construction Condition: Vegetation removal and soil disturbance shall be limited to the minimum amount necessary for project implementation, especially where the existing access road comes near the artificial wetland, and where the proposed pipeline would cross both the artificial wetland and the ephemeral drainage. Where soils are disturbed and/or vegetation removed on the project site, such as in the construction staging area, the site shall be returned to pre-project conditions (i.e., return site contours to pre-project profiles, restore original grades where possible, lightly compact loose soils or aerate compacted soils) where necessary. Where grading occurs, 12 inches of topsoil shall be salvaged and respread in graded areas as appropriate. When natural vegetation is disturbed, small areas (e.g., less than 100 square feet in size) shall be allowed to re-vegetate passively, while larger disturbed areas (e.g., more than 100 square feet in size or in areas prone to erosion such as sloped areas) shall be re-seeded with locally available native grasses and forbs (as needed).	Tesla Portal
Impact 4.6-3: Impacts on special-status species, direct mortality and/or habitat effects	Tesla Portal: PSM Thomas Shaft: PSM	Mitigation Measure 4.6-3a – Worker Awareness Program: Prior to the commencement of construction activities, a qualified biologist shall conduct a worker awareness program (environmental education) to inform project workers of the sensitive habitat and species potentially found onsite and their responsibilities with regards to protecting those sensitive biological resources.	Tesla Portal and Thomas Shaft
		Mitigation Measure 4.6-3b – Conduct Pre-Construction Surveys for San Joaquin Whipsnake and California Horned Lizard: Prior to the start of construction, a qualified biologist shall conduct San Joaquin whipsnake surveys, and surveys for California horned lizard. These species are of very limited distribution within San Joaquin County, primarily isolated locations outside of anticipated development areas. Therefore, if discovered on a	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		project site and prior to ground disturbance, ITMMs shall be formulated by the SJMSCP TAC and approved by the San Joaquin Council of Governments (SJCOG) with the concurrence of the Permitting Agencies' representatives on the TAC. ITMMs may consist of preconstruction surveys, avoidance techniques and/or buffer areas.	
		Mitigation Measure 4.6-3c – Implement Incidental Take Minimization Measures for San Joaquin Kit Fox: SFPUC shall implement the ITMMs identified for the San Joaquin kit fox under the SJMSCP to reduce the level of impact on the San Joaquin kit fox. Mitigation measures defined by the SJMSCP and the USFWS to protect the San Joaquin kit fox include the following: • A qualified biologist with demonstrated experience in kit fox biology, identification, and survey techniques shall conduct preconstruction surveys two calendar weeks to 30 calendar days prior to commencement of ground disturbance. Surveys shall be conducted by qualified biologists. When surveys identify potential dens (potential dens are defined as burrows at least four inches in diameter which open up within two feet), potential den entrances shall be dusted for three calendar days to register track of any San Joaquin kit fox present. If no San Joaquin kit fox activity is identified, potential dens may be destroyed. • If San Joaquin kit fox activity is identified, then dens shall be monitored to determine if occupation is by an adult fox only or is a natal den (natal dens usually have multiple openings). If the den is occupied by an adult only, the den may be destroyed when the adult fox has moved or is temporarily absent. If the den is a natal den, a buffer zone of 250 feet shall be maintained around the den until the biologist determines that the den has been vacated. • Where San Joaquin kit fox are identified, the provisions of the U.S. Fish and Wildlife Service's published "Standardized Recommendations for Protection of the San Joaquin kit fox Prior to or During Ground Disturbance" shall apply (except that preconstruction survey protocols shall remain as established in this paragraph). These standards include provisions for educating construction workers regarding the kit fox, keeping heavy equipment operating at safe speeds, checking construction pipes for kit fox occupation during construction and similar low or no-cost activities.	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		Mitigation Measure 4.6-3d – Conduct Pre-Construction Surveys to Determine Presence/Absence of San Joaquin Pocket Mouse: Prior to the start of construction activities, a qualified biologist shall conduct surveys to determine the presence or absence of San Joaquin pocket mouse. If the species is not found, then no other mitigation is required. If the species is found in or near potential work areas, the SFPUC will coordinate with the SJMSCP TAC to formulate avoidance measures, such as buffer areas and limiting the time and extent of construction activities.	Tesla Portal and Thomas Shaft
		Mitigation Measure 4.6-3e – Breeding Season Surveys: Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below: • If project schedule permits, a qualified biologist will survey for burrows and burrowing owls during the breeding season (February 1 to August 31), immediately preceding construction. Surveys will be conducted within 500 feet of the project boundary (access permitting) in accordance with the California Burrowing Owl Consortium (1993) guidelines or as otherwise determined by CDFG. Burrows would be inspected for signs of owl activity (tracks, pellets, feathers, etc.). The locations of burrowing owl sightings, occupied burrows, and burrows with signs of owl activity will be marked on a map of the project area at a scale sufficient to accurately show the distance of active burrows to the limits of construction. Surveys will be conducted on at least four separate dates during the breeding season in areas where suitable burrows are present. If possible, surveys will be conducted during the peak of the burrowing owl breeding season, generally between April 15 and July 15. • If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with CDFG, as to whether work will affect the occupied burrows or disrupt reproductive behavior. • If it is determined that construction will not affect occupied burrows or disrupt breeding behavior, construction will proceed without any restrictions or mitigation measures.	Tesla Portal
		Mitigation Measure 4.6-3f – Winter Surveys: Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below:	Tesla Portal

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		• If birds are not observed during breeding season surveys, or if breeding season surveys are infeasible due to project scheduling, or if construction will occur during the wintering season, a winter survey will be conducted to identify non-breeding residents of the project site. Winter surveys will be conducted within 500 feet of the project site (access permitting) or as otherwise determined by CDFG during the period when wintering owls are most likely to be present (December 1 to January 31). The locations of burrowing owl sightings, occupied burrows, and burrows with signs of owl activity will be marked on a map of the project area at a scale sufficient to accurately show the distance of active burrows to the limits of construction. • If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with CDFG, as to whether or not work will affect the occupied burrows. • If it is determined that construction will not affect occupied burrows, construction will proceed without any restrictions or mitigation measures. • If it is determined that construction will affect occupied burrows, the subject owls will be passively relocated from the occupied burrow(s) using one-way doors prior to the onset of breeding season. Owls will be encouraged to relocate to alternate burrows that are at least 160 feet from the construction limits. One alternate natural or artificial burrow for each burrow excavated will be in place at least one week before one-way doors are installed on occupied burrows. One-way doors will be in place for a minimum of 48 hours before burrows are excavated. <u>Mitigation Measure 4.6-3g – Fall Surveys</u>: Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below: • If surveys must be conducted between September 1 and November 30 (which is outside of the time windows specified above), a qualified biologist will conduct a survey for burrows and burrowing owls no more than thirty (30) days prior to ground-disturbing activity. If necessary, resident owls will be passively relocated from occupied burrows, as described above. If construction activities are still ongoing beyond November 30, then winter surveys will be conducted during December and January.	Tesla Portal

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		Mitigation Measure 4.6-3h – Conduct Pre-Construction Surveys for Swainson's Hawk: A qualified biologist shall conduct a preconstruction survey for Swainson's hawk, prior to the commencement of any ground disturbing construction activities (e.g., grass/vegetation/brush/tree removal, soil excavation, grading, vehicle access, staging of materials or vehicles, large scale materials off-haul or delivery, construction of temporary or permanent access roads). In the case that Swainson's hawks are found nesting in the area, the SFPUC will notify CDFG. At a minimum the following mitigations regarding Swainson's hawk, as listed from the SJMSCP, will be implemented: • If a nest tree becomes occupied during construction activities, then all construction activities shall remain a distance of two times the dripline of the tree, measured from the nest. • If any nest trees need to be removed, they may be removed between September 1 and February 15, when the nests are unoccupied. The following two measures will also be implemented: • If any unoccupied nests are found during preconstruction surveys, these nests may be removed when the nests are unoccupied. • If any occupied nests are found during preconstruction surveys, then all construction activities shall remain at a distance of ¼ mile (1,320 feet), unless CDFG agrees to other equally effective measures (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc).	Tesla Portal
		Mitigation Measure 4.6-3i – Implement Incidental Take Minimization Measures for White-Tailed Kite: SFPUC shall implement the ITMM identified for the white-tailed kite under the SJMSCP, which consists of the following: • A qualified biologist shall conduct preconstruction surveys and investigate all potential nesting trees on the project site (e.g., especially tree tops 15-59 feet above the ground in oak, willow, eucalyptus, cottonwood, or other deciduous trees), during the nesting season (February 15 to September 15) whenever white-tailed kites are noted on site or within the vicinity of the project site during the nesting season.	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		• If the species is found nesting, a setback of 100 feet from nesting areas shall be established and maintained during the nesting season for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective measures (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc.) and CDFG shall be notified of the proposed buffer zone. This setback applies whenever construction or other ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.	
		Mitigation Measure 4.6-3j – Implement Incidental Take Minimization Measures for California Horned Lark and Northern Harrier: SFPUC shall implement the ITMM identified for the California horned lark and northern harrier under the SJMSCP, which consists of the following: • A qualified biologist shall conduct a preconstruction survey and investigate all potential nesting trees to determine the presence or absence of the species on the project site. • If species are found, a setback of 500 feet from nesting areas shall be established and maintained during the nesting season (February 16 – August 31) for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective measures (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc.), or offsite compensation shall be provided, and CDFG shall be notified of the proposed buffer zone. If a setback is used, this setback would apply whenever construction or other ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.	Tesla Portal and Thomas Shaft
		Mitigation Measure 4.6-3k – Conduct Pre-Construction Surveys for Golden Eagle: Prior to the start of construction, a qualified biologist shall conduct golden eagle surveys as required by the SJMSCP. Additionally, SFPUC shall implement the ITMM identified for the golden eagle under the SJMSCP, which consists of the following:	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		• When a site inspection indicates the presence of a nesting golden eagle, CDFG will be notified and a setback of 500 feet from the nesting area shall be established and maintained during the nesting season (normally approximately February 1 – June 30) for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective measures (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc.). This setback applies whenever construction or other ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.	
		Mitigation Measure 4.6-3l – Conduct Pre-Construction Surveys for Ferruginous Hawk and Prairie Falcon: Prior to the start of construction, a qualified biologist shall conduct surveys for ferruginous hawk and prairie falcon as required by the SJMSCP. These species currently do not nest in San Joaquin County and are not expected to nest in the County over the life of the SJMSCP. Therefore, in the highly unlikely event that one of these species is found nesting on a project site, SFPUC shall notify CDFG of the proposed buffer zone and a setback of 500 feet from the nesting area shall be established and maintained for the period encompassing nest building and continuing until fledglings leave the nests, unless CDFG agrees to other equally effective measures. ITMMs shall be formulated prior to ground disturbance by the TAC and approved by the JPA with the concurrence of the Permitting Agencies' representatives on the TAC in accordance with the SJMSCP's Adaptive Management Plan. ITMMs may consist of preconstruction surveys, avoidance techniques, and buffer areas.	Tesla Portal and Thomas Shaft
Cultural Resources			
Impact 4.7-1: Potential to disturb or destroy paleontological resources.	Tesla Portal: PSM Thomas Shaft: PSM	Mitigation Measure 4.7-1a – Paleontological Monitoring During Excavation: The SFPUC shall retain a qualified professional paleontologist to monitor excavations starting at the depth of 10 feet deep during construction at the Tesla Portal site for paleontological resources. Monitoring shall continue at the Tesla Portal site until the supervising qualified paleontologist determines that no native sediments are present or that significant paleontological resources are not likely to be discovered.	Tesla Portal

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		Mitigation Measure 4.7-1b Suspend Construction Work if Paleontological Resource is Identified: This mitigation measure builds on SFPUC Construction Measure #9 for cultural resources, which requires that construction work will be suspended immediately if there is any indication of a paleontological resource. When a paleontological resource (fossilized invertebrate, vertebrate, plant or micro-fossil) is discovered at any of the project sites, an appointed representative of the SFPUC will notify a qualified paleontologist, who will document the discovery as needed, evaluate the potential resource, and assess the significance of the find under the criteria set forth in Section 15064.5 of the CEQA Guidelines. When a fossil is found during construction, excavations within 50 feet of the find will be temporarily halted or diverted until the discovery is examined by a qualified paleontologist, in accordance with Society of Vertebrate Paleontology standards (Society of Vertebrate Paleontology, 1995). The paleontologist will notify the SFPUC to determine procedures to be followed before construction is allowed to resume at the location of the find. If the SFPUC determines that avoidance is not feasible, the paleontologist will prepare an excavation plan for mitigating the effects of the project.	Tesla Portal and Thomas Shaft
Impact 4.7-2: Potential to disturb or destroy unknown prehistoric archaeological resources or human remains.	Tesla Portal: PSM Thomas Shaft: PSM	Mitigation Measure 4.7-2a – Accidental Archaeological Discovery: SFPUC Standard Construction Measure #9 for cultural resources requires that construction activities be suspended immediately if there is any indication of an archaeological resource. To avoid any potential adverse effect from the proposed project on accidentally discovered buried or submerged historical resources as defined in CEQA Guidelines Section 15064.5(a)(c), the SFPUC shall distribute the Planning Department archaeological resource "ALERT" sheet to the project prime contractor; to any project subcontractor (including demolition, excavation, grading, foundation, pile driving, etc. firms); or utilities firm involved in soil disturbing activities within the project site. Prior to any soil disturbing activities being undertaken, each contractor is responsible for ensuring that the "ALERT" sheet is circulated to all field personnel including, machine operators, field crew, pile drivers, supervisory personnel, etc. The SFPUC shall provide the Environmental Review Officer (ERO) with a signed affidavit from the responsible parties (prime contractor, subcontractor(s), and utilities firm) confirming that all field personnel have received copies of the "ALERT" sheet.	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		Should any indication of an archaeological resource be encountered during any soils disturbing activity of the project, the contractor and/or the SFPUC will immediately notify the ERO and will immediately suspend any soils disturbing activities within 100 feet of the discovery until the ERO has determined what additional measures should be undertaken. If the ERO determines that an archeological resource may be present within the project site, the SFPUC shall retain the services of a qualified archeological consultant. The archeological consultant shall advise the ERO as to whether the discovery is an archeological resource that retains sufficient integrity, and is of potential scientific/historical/cultural significance. If an archeological resource is present, the archeological consultant shall identify and evaluate the archeological resource. The archeological consultant shall make a recommendation as to what action, if any, is warranted. Based on this information, the ERO may require, if warranted, specific additional measures to be implemented by the SFPUC. Measures might include: preservation in situ of the archeological resource; an archaeological monitoring program; or an archeological evaluation program. If an archaeological monitoring program or archeological evaluation program is required, it shall be consistent with the MEA WSIP Archaeological Guidance (San Francisco Planning Department, 2008a) for such programs. The ERO may also require that the SFPUC immediately implement a site security program if the archeological resource is at risk from vandalism, looting, or other damaging actions. The project archeological consultant shall submit an accidental discovery Archaeological Data Recovery Report (ADRR) to the ERO, which, in addition to the usual contents of the ADRR, includes an evaluation of the historical significance of any discovered archeological resource, as well as describing the archeological and historical research methods employed in the archeological monitoring/data recovery program(s) undertaken, and presenting, analyzing, and interpreting the recovered data. Information that may put at risk any archeological resource shall be provided in a separate removable insert within the final report. Once approved by the ERO, copies of the ADRR shall be distributed as follows: the relevant California Historical Resources Information System Information Center shall receive one (1) copy and the ERO shall receive a copy of the transmittal letter of the	

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		ADRR to the Information Center. The MEA shall receive three copies of the ADRR along with copies of any formal site recordation forms (CA DPR 523 series) and/or documentation for nomination to the National Register of Historic Places/California Register of Historical Resources. The SFPUC shall receive copies of the ADRR in the number requested. In instances of high public interest in or the high interpretive value of the resource, the ERO may require a different final report content, format, and distribution than that presented above.	
		Mitigation Measure 4.7-2b – Treatment of Human Remains: The treatment of human remains and of associated or unassociated funerary objects discovered during any soils disturbing activity shall comply with applicable State laws. This shall include immediate notification of the San Joaquin County Coroner and in the event of the coroner's determination that the human remains are Native American, notification of the California State Native American Heritage Commission (NAHC) who shall appoint a Most Likely Descendant (MLD) (Public Resources Code Section 5097.98). The archaeological consultant, SFPUC, and MLD shall make all reasonable efforts to develop an agreement for the treatment of, with appropriate dignity, human remains and associated or unassociated funerary objects (CEQA Guidelines Section 15064.5(d)). The agreement should take into consideration the appropriate excavation, removal, recordation, analysis, custodianship, curation, and final disposition of the human remains and associated or unassociated funerary objects. California Public Resources Code allows 24 hours to reach agreement on these matters. If the MLDs and the other parties do not agree on the reburial method, the project will follow Section 5097.98(b) of the California Public Resources Code which states, "the landowner or his or her authorized representative shall reinter the human remains and items associated with Native American burials with appropriate dignity on the property in a location not subject to further subsurface disturbance."	Tesla Portal and Thomas Shaft
Impact 4.7-3: Potential to cause a substantial adverse change in the significance of a historical resource.	Tesla Portal: PSM Thomas Shaft: LS	Mitigation Measure 4.7-3 – Architectural Resources Protection Plan: The SFPUC shall retain a qualified historian to prepare a plan that specifies procedures for protecting historical resources at the Tesla Portal site during construction activities. The plan shall include a monitoring method to be employed by the construction contractor while working near these resources. At a minimum, the plan shall address the operation of construction	Tesla Portal

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		equipment near or adjacent to the historical resource, storage of construction materials away from the resource, and education/training of construction workers about the significance of the historical resources. The plan shall also require the construction of a temporary protective barrier around the Southwest Valve House, such as construction fencing and/or vertical and horizontal netting to prevent physical damage to the valve house.	
Air Quality			
Impact 4.9-1: Construction emissions of criteria pollutants	Tesla Portal: PSM Thomas Shaft: PSM	Mitigation Measure 4.9-1a – SJVAPCD Dust Control Measures: The following applicable general San Joaquin Valley Air Pollution Control District (SJVAPCD) recommended mitigation measures will be implemented to reduce emissions of fugitive PM_{10} dust from construction activities at both project sites, as specified in the Guide to Assessing and Mitigating Air Quality Impacts (GAMAQI), and in accordance with Regulation VIII Rules addressing construction (Rules 8011, 8021, 8031, 8041, 8051, 8061, and 8071). *SJVAPCD Regulation VIII Basic Control Measures:* • Adhere to the recordkeeping requirements specified in Rule 8011 (Section 6.2) for days that control measures are implemented. • Submit a Dust Control Plan (form available from SJVAPCD) in accordance with Rule 8021. • All disturbed areas, including storage piles that are not being actively utilized for construction purposes, shall be effectively stabilized of dust emissions using water, chemical stabilizer/suppressant, covered with a tarp or other suitable cover, or vegetative ground cover in accordance with Rule 8031. • All onsite unpaved access roads shall be effectively stabilized of dust emissions using water or chemical stabilizer/suppressant in accordance with Rule 8031. • All land clearing, grubbing, scraping, excavation, land leveling, grading, cut and fill, and demolition activities shall be effectively controlled of fugitive dust emissions utilizing application of water or by presoaking in accordance with Rule 8021. • Limit Visible Dust Emissions (VDE) to 20% opacity by applying water or chemical/organic stabilizers/suppressants or construct and maintain wind barriers	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		sufficient to limit VDE to 20% opacity. If utilizing wind barriers, water or chemical suppressants shall also be implemented. • When materials are transported offsite, all material shall be covered, or effectively wetted to limit visible dust emissions, and at least 6 inches of freeboard space from the top of the container shall be maintained in accordance with Rule 8031. • All operations shall limit or expeditiously remove the accumulation of mud or dirt from adjacent public streets at the end of each workday. The use of dry rotary brushes is expressly prohibited except where preceded or accompanied by sufficient wetting to limit the visible dust emissions. Use of blower devices is expressly forbidden in accordance with Rule 8041. • Following the addition of materials to, or the removal of materials from, the surface of outdoor storage piles, said piles shall be effectively stabilized of fugitive dust emissions utilizing sufficient water or chemical stabilizer/suppressant in accordance with Rule 8031. • A trackout control device shall be installed and maintained at all access points to paved public roads or a carryout and trackout prevention procedure, which as been demonstrated to the satisfaction of the APCO and U.S. EPA, shall be implemented in accordance with Rule 8041. • Trackout shall be immediately removed when it extends 50 or more feet from the nearest unpaved surface exit point of the site and at the end of each workday in accordance with Rule 8041. *SJVAPCD Enhanced Control Measures* • Traffic speeds on unpaved roads shall be limited to 15 mph and speed limit signs shall be posted in accordance with Rule 8021, Section 5.3.	
		Mitigation Measure 4.9-1b – SJVAPCD Exhaust Control Measures: The following mitigation measures will be implemented during construction of the proposed project to reduce exhaust emissions: *(1) SJVAPCD Guide to Assessing and Mitigating Air Quality Impacts Mitigation Measures:* To limit exhaust emissions within the San Joaquin Region, the SJVAPCD specifies the	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		following exhaust controls for heavy-duty equipment (scrapers, graders, trenchers, earthmovers, etc.). The SFPUC will include these measures, where feasible and applicable, in contract specifications: • Idling time (e.g., 5-minute maximum) shall be minimized. • The hours of operation of heavy-duty equipment and/or the amount of equipment in use shall be limited. • Activity management (e.g., rescheduling activities to reduce short-term impacts) shall be implemented. *(2) Regulation IX – Mobile and Indirect Sources, Rule 9510 Mitigation Measures:* Rule 9510 applies to any project subject to discretionary approval by a public agency that ultimately results in the construction of a new building, facility, or structure or reconstruction of a building, facility, or structure for the purpose of increasing capacity or activity and also involving 9,000 square feet of space. Rule 9510 requires exhaust emissions for construction equipment greater than 50 horsepower used or associated with a development project to be reduced by the following amounts from the statewide average as estimated by the California Air Resources Board (CARB): • 20% of the total NO_X emissions • 45% of the total PM_{10} exhaust emissions An applicant may reduce construction emissions on site by using less polluting construction equipment, which can be achieved by utilizing add-on controls, cleaner fuels, or newer lower emitting equipment. The requirements listed above can also be met through the payment of an offsite emissions reduction fee. The following mitigation measures will be selectively applied to achieve compliance with the emission reductions set forth by Rule 9510: • Selected construction equipment with engines equal to or greater than 50 horsepower will: o Be equipped with Tier 2 diesel engines as defined in Title 13, CCR, §2423 o Must be equipped with verified Level 3 (at least 85% reduction of PM from the baseline emission level) Diesel Emission Control Strategies as defined in	

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		Title 13, CCR, §2700 through 2710 • All construction vehicles will undergo monthly maintenance. Preventive maintenance includes complying with the manufacturer's service recommendations, using recommended types of fuel, maintaining proper fluid levels (such as oil, coolant, brake, and transmission), ensuring proper tire pressure, working signals, lights (including headlamps, turn-signal lights, tail lights, and brake lights), and brakes.	
Noise and Vibration			
Impact 4.10-1: Disturbance from temporary construction-related noise increases	Tesla Portal: PSM Thomas Shaft: LS	Mitigation Measure 4.10-1 – Vacate SFPUC Caretaker's Residence at the Tesla Portal Site: The SFPUC caretaker's residence at Tesla Portal shall be vacated during hours when construction activities at the site would produce daytime sound levels in excess of the speech interference criterion (an exterior noise level of 70 dBA) or nighttime sound levels in excess of the sleep interference criterion (an exterior noise level of 60 dBA).	Tesla Portal
Impact 4.10-3: Disturbance due to construction-related vibration	Tesla Portal: PSM Thomas Shaft: N/A	Mitigation Measure 4.10-2 – Maintain Structural Integrity of San Joaquin Pipelines The construction contractor shall perform construction (cutting and connecting a new manifold) at the tie-in of the proposed UV Building to San Joaquin Pipelines 1 and 2 in to maintain the structural integrity of the pipelines.	Tesla Portal
Energy Resources			
Impact 4.14-2: Long-term energy use during operation	Tesla Portal: PSM Thomas Shaft: PSM	Mitigation Measure 4.14-1 – Incorporate Energy Efficiency Measures: Consistent with the Energy Action Plan II priorities for reducing energy usage, the SFPUC shall ensure that energy efficient equipment is used in the proposed project at the Tesla Portal and the Thomas Shaft sites. A repair and maintenance plan shall also be prepared for each facility to minimize power use. Cooling, heating and ventilation rates will meet the standards of the American Society of Heating, Refrigeration and Air-Conditioning Engineers, California Building Code and the California Building Energy Efficiency Code. All ductwork will comply with Sheet Metal and Air Conditioning Contractors' National Association objectives. The SFPUC shall also include the use of renewable energy, such as solar power, at the Tesla Treatment Facility.	Tesla Portal and Thomas Shaft
Cumulative Effects – Traffic	Tesla Portal: PSM	Mitigation Measure 4.15-1a – SFPUC WSIP Project Construction Coordinator: Due to the	Tesla Portal and

	Thomas Shaft: PSM	potential for overlapping project activities in the western side of the SFPUC San Joaquin Region near the project sites, and the potential for construction vehicles to affect travel within and across different WSIP regions, the SFPUC shall identify a qualified construction coordinator responsible for coordinating project-specific traffic control plans, and for developing a public information campaign (e.g., internet website, radio and newspaper updates) to inform the public of construction activities, detour routes, and alternate routes. Throughout the seven-year construction schedule for the San Joaquin WSIP projects, the SFPUC construction coordinator shall work with local and regional agencies to pursue additional traffic mitigation measures to minimize local and regional traffic impacts and will incorporate these measures into the project-specific traffic control plans, as appropriate.	Thomas Shaft
		Mitigation Measure 4.15-1b – Combined San Joaquin Regional Traffic Control Plan: Due to the potential for overlapping project schedules in the San Joaquin Region near the project sites, the SFPUC will develop, or the SFPUC's construction contractor(s) shall be required to develop, a San Joaquin Regional Traffic Control Plan. This plan will coordinate the project-specific traffic control plans that shall be developed for individual WSIP projects in the San Joaquin Region, and identify additional measures, if necessary, to minimize the combined impacts of multiple WSIP project construction traffic on I-580, Chrisman Road, and West Vernalis Road. As applicable, these measures shall be developed consistent with the standards of San Joaquin County, Stanislaus County, and Caltrans and could include: • Additional traffic control devices, such as traffic signals at key intersections providing access to local roadways and land uses • Additional traffic control personnel at key locations to facilitate vehicular traffic flow during peak periods of truck activity • Adjustments in truck arrival and departure schedules for the various facilities (e.g., staggering departures)	Tesla Portal and Thomas Shaft
		Mitigation Measure 4.15-1c – Coordination with Other Agencies: The SFPUC WSIP construction coordinator shall coordinate with Caltrans, other county agencies, and local jurisdictions responsible for reviewing and/or approving the construction of other identified private and public development projects. Coordination efforts will be focused on minimizing traffic impacts on local access roads, particularly local streets where sensitive receptors (e.g., schools, residences, or hospitals) are located.	Tesla Portal and Thomas Shaft

- San Francisco Public Utilities Commission (SFPUC), Water System Improvement Program California Environmental Quality Act Findings: Findings of Fact, Evaluation of Mitigation Measures and Alternatives, and Statement of Overriding Considerations, SFPUC Resolution No. 08-0200, October 30, 2008c.

CHAPTER 2
Introduction

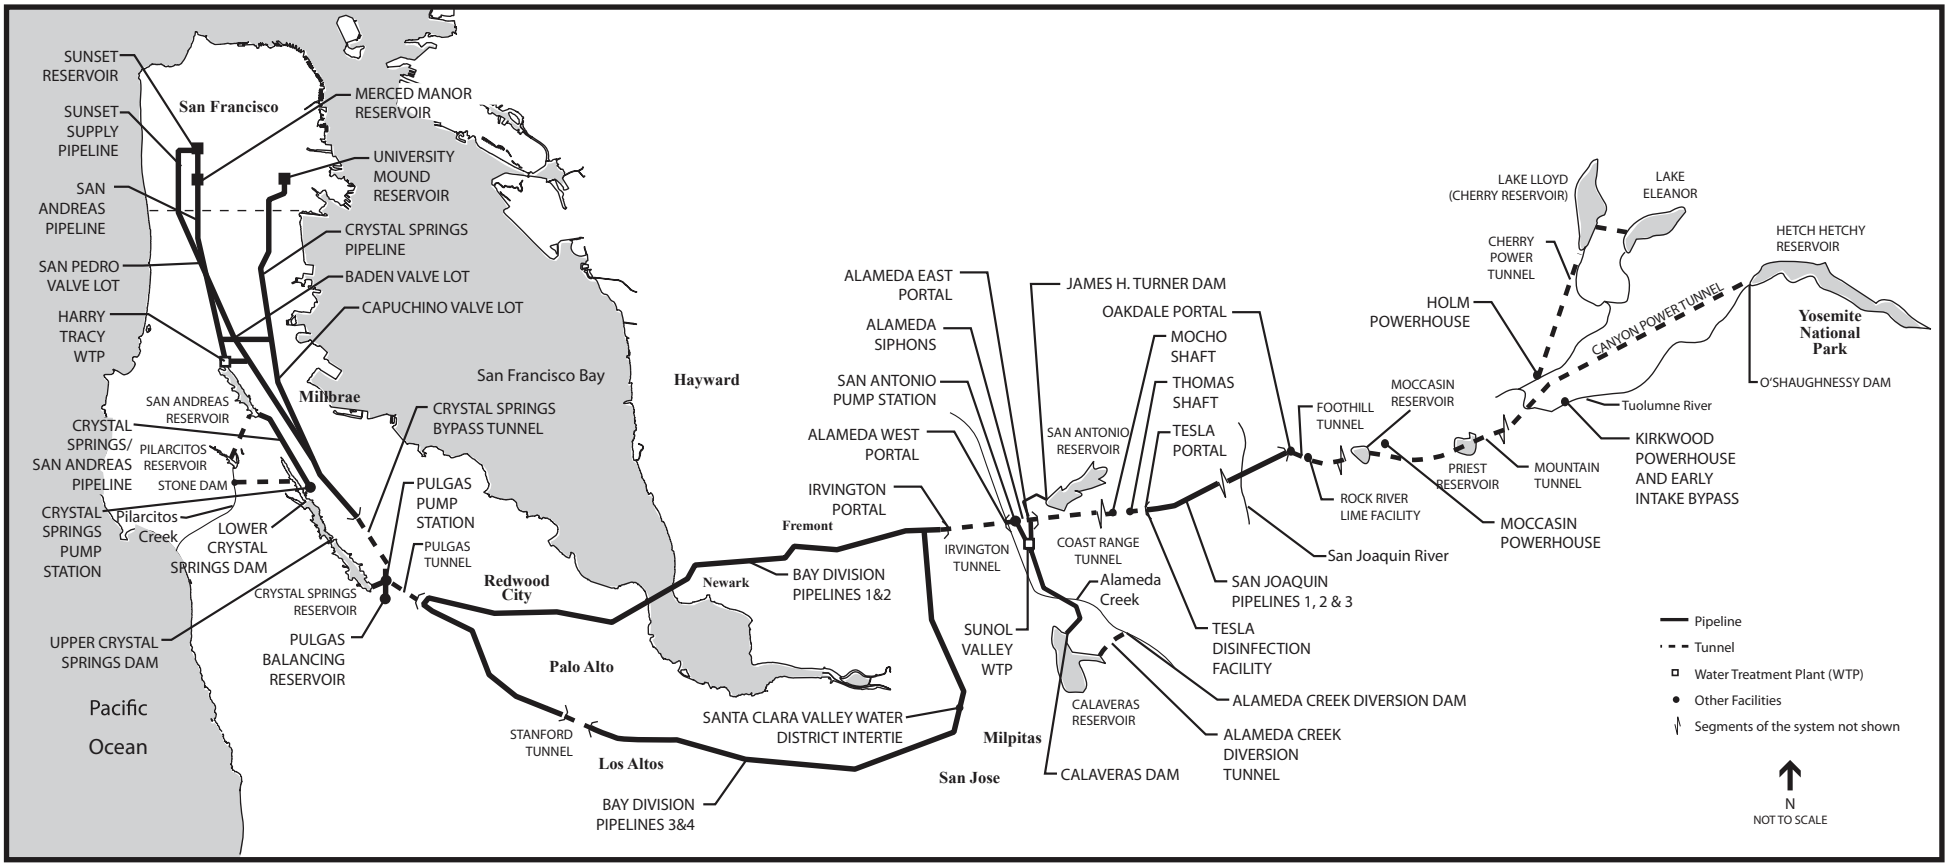
The San Francisco Public Utilities Commission (SFPUC) proposes the *San Joaquin Regional Water Quality Improvement Project* (project) to meet water quality regulatory requirements and reduce facility vulnerability to seismic events. The project proposes to construct and operate three new facilities at two existing sites located along the SFPUC's regional water system. At the Tesla Portal site, among other improvements, the existing building that contains the Tesla Portal Hypochlorite Station would be replaced with a new Chemical Process Building and Office/Control Building. In addition, an ultraviolet (UV) facility would be constructed, which would disinfect water using a series of UV light arrays. At the Thomas Shaft site, the Lawrence Livermore Water Quality Improvements would upgrade existing water treatment with a UV facility to meet disinfection requirements of the Surface Water Treatment Rule and the Long Term 2 Enhanced Surface Water Treatment Rule.

2.1 Project Background

2.1.1 SFPUC Regional Water System Overview

The City and County of San Francisco (CCSF), through the SFPUC, owns and operates a regional water system that extends from the Sierra Nevada to San Francisco and serves 2.4 million people in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne counties. The regional water system consists of water conveyance, treatment, and distribution facilities, and delivers water to retail and wholesale customers. The existing regional system includes over 280 miles of pipelines, over 60 miles of tunnels, 11 reservoirs, five pump stations, and two water treatment plants. The SFPUC currently delivers an annual average of about 265 million gallons per day (mgd) of water to its customers. The source of the water supply is a combination of local supplies from streamflow and runoff in the Alameda Creek watershed and in the San Mateo and Pilarcitos Creeks watersheds (referred to together as the Peninsula watersheds), augmented with imported supplies from the Tuolumne River watershed. Local watersheds provide about 15 percent of total supplies and the Tuolumne River provides the remaining 85 percent. Figure 2-1 (SFPUC Regional Water System) illustrates the general location of the SFPUC regional system and water supply watersheds.

The SFPUC serves about one-third of its water supplies directly to retail customers, primarily in San Francisco, and about two-thirds of its water supplies to wholesale customers by contractual agreement. The wholesale customers are largely represented by the Bay Area Water Supply and Conservation Agency, which consists of 27 total customers, shown in Figure 2-2 (SFPUC Water Service Area – San Francisco and SFPUC Wholesale Customers). Some of these wholesale



SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT EIR

SFPUC Regional Water System

Figure 2-1

customers have other sources of water in addition to what they receive from the SFPUC regional system, while others rely completely on the SFPUC for supply.

2.1.2 SFPUC Water System Improvement Program

On October 30, 2008, the SFPUC adopted a regional Water System Improvement Program (known as the "Phased WSIP Variant") (refer to www.sfwater.org; SFPUC, 2008e; also see SFPUC Resolution No. 08-0200). The adopted WSIP would improve the regional system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area through the year 2018 and would establish level of service goals and system performance objectives. The proposed program area spans seven counties—Tuolumne, Stanislaus, San Joaquin, Alameda, Santa Clara, San Mateo, and San Francisco.

The WSIP includes a water supply strategy, modifications to system operations, and construction of a series of facility improvement projects. The proposed project, along with several other facility improvement projects, is a component of the WSIP.[1] The overall goals of the WSIP are to maintain high-quality water; reduce vulnerability to earthquakes; increase delivery reliability and improve the ability to maintain the system; meet customer purchase requests in nondrought and drought periods; enhance sustainability in all system activities; and achieve a cost-effective, fully operational system (refer to Table 2-1). To further these program goals, the WSIP also includes objectives that address system performance in the areas of water quality, seismic reliability, delivery reliability, and water supply through the year 2018.

TABLE 2-1
WSIP GOALS AND OBJECTIVES

Program Goal	System Performance Objective
Water Quality – *maintain high quality water*	• Design improvements to meet current and foreseeable future federal and state water quality requirements. • Provide clean, unfiltered water originating from Hetch Hetchy Reservoir and filtered water from local watersheds. • Continue to implement watershed protection measures.

[1] The proposed project is listed as three separate projects in the WSIP PEIR: the Tesla Portal Disinfection Facility, the Hetch Hetchy Advanced Disinfection, and the Lawrence Livermore Supply Improvements. For purposes of this EIR, these three projects are evaluated as one project given their geographic proximity, construction schedule, and the interrelated function of the two proposed facilities at the Tesla Portal site.

TABLE 2-1
WSIP GOALS AND OBJECTIVES

Seismic Reliability – *reduce vulnerability to earthquakes*	• Design improvements to meet current seismic standards. • Deliver basic service to the three regions in the service area (East/South Bay, Peninsula, and San Francisco) within 24 hours after a major earthquake. Basic service is defined as average winter-month usage, and the performance objective for the regional system is 229 million gallon per day (mgd). The performance objective is to provide delivery to at least 70 percent of the turnouts (i.e., water diversion connecting points from the regional system to customers) in each region, with 104, 44 and 81 mgd delivered to East/South Bay, Peninsula, and San Francisco regions, respectively. • Restore facilities to meet average-day demand of up to 300 mgd within 30 days after a major earthquake.
Delivery Reliability – *increase delivery reliability and improve the ability to maintain the system*	• Provide operational flexibility to allowed planned maintenance shutdown of individual facilities without interrupting customer service. • Provide operational flexibility to minimize the risk of service interruption due to unplanned facility upsets or outages. • Provide operational flexibility and system capacity to replenish local reservoirs as needed. • Meet estimated average annual demand of up to 300 mgd under the conditions of one planned shutdown of a major facility for maintenance concurrent with one unplanned facility outage due to a natural disaster, emergency, or facility failure/upset.
Water Supply – *meet customer water needs in nondrought and drought periods*	• Meet average annual water demand of 265 mgd from the SFPUC watersheds for retail and wholesale customers during nondrought years for system demands through 2018. • Meet dry-year delivery needs through 2018 while limiting rationing to a maximum 20 percent systemwide reduction in water service during extended droughts. • Diversify water supply options during nondrought and drought periods. • Improve use of new water sources and drought management, including groundwater, recycled water, conservation, and transfers
Sustainability – *enhance sustainability in all system activities*	• Manage natural resources and physical systems to protect watershed ecosystems. • Meet, at a minimum, all current and anticipated legal requirements for protection of fish and wildlife habitat. • Manage natural resources and physical systems to protect public health and safety.
Cost-effectiveness – achieve a cost-effective, fully operational system	• Ensure cost-effective use of funds. • Maintain gravity-driven system. • Implement regular inspection and maintenance program for all facilities.

Source: SFPUC, Resolution No. 08-0200, 2008

To address the potential environmental impacts of the WSIP, the San Francisco Planning Department prepared a Program EIR (PEIR), which was certified by the San Francisco Planning Commission in its Motion No. 17734 on October 30, 2008 (San Francisco Planning Department, 2008b). At a program-level of detail, the PEIR evaluated the environmental impacts of the WSIP and, at a program level of detail, it evaluated the environmental impacts of the WSIP's facility improvement projects.

Not to Scale

SFPUC Water Service Area - San Francisco and SFPUC Wholesale Customers

Figure 2-2

2.1.3 San Joaquin Regional Water System Facilities

The proposed project is located at two existing facility sites along the SFPUC's regional water system: the Tesla Portal site and the Thomas Shaft site. Both of these sites are located in unincorporated San Joaquin County (refer to Figure 2-3, Vicinity Map), and are part of the SFPUC's San Joaquin Region, described below.

The Oakdale Portal is the connection between the western end of Foothill Tunnel and the San Joaquin Pipelines. From Oakdale Portal, water from the Hetch Hetchy facilities is conveyed across the San Joaquin Valley by gravity in three parallel pipelines known as San Joaquin Pipelines Nos. 1, 2, and 3 (built in 1932, 1953, and 1968, respectively). The pipelines pass through Modesto, under the San Joaquin River, and past Tracy to Tesla Portal on the west side of the San Joaquin Valley. The current capacity of the three pipelines is approximately 290 mgd; however, when originally planned in 1912, the San Joaquin Pipeline system was envisioned with an ultimate nominal capacity of 400 mgd.

The San Joaquin Pipelines end at Tesla Portal and connect to the Coast Range Tunnel. Tesla Portal, which is located on the east side of the Coast Ranges, is also the location of the Tesla Portal Hypochlorite Station, where Hetch Hetchy water is disinfected with chlorine and monitored for water quality. From Tesla Portal, the chlorinated Hetch Hetchy water is transported through the Coast Range Tunnel to system facilities in the Sunol Valley. Water delivery to Lawrence Livermore National Laboratory, a retail customer, occurs from the Coast Range Tunnel via two access shafts from the tunnel, Thomas Shaft and Mocho Shaft. At Thomas Shaft, a standby/backup chlorination facility provides disinfection in the event of operational difficulty at Tesla Portal. The 25-mile-long Coast Range Tunnel ends at the Alameda East Portal in the Sunol Valley. Again, water deliveries are transported entirely by gravity across the San Joaquin Region to the Sunol Valley.

2.2 Purpose of the Environmental Impact Report

The San Francisco Planning Department, Major Environmental Analysis (MEA) Division, determined that implementation of the proposed project could have a significant effect on the environment and, therefore, requires preparation of an Environmental Impact Report (EIR) in accordance with the requirements of the California Environmental Quality Act (CEQA) (California Public Resources Code Section 21000 et seq.) and its implementing guidelines (CEQA Guidelines) (Title 14, California Code of Regulations, Section 15000 et seq.). CEQA requires that, before a decision can be made by a state or local government agency to approve a project with potentially significant environmental effects, an EIR must be prepared that fully describes the environmental effects of the project. An EIR is an informational document for use by governmental agencies and the public. It is intended to identify and evaluate potential physical environmental impacts associated with a proposed project, to identify mitigation measures to reduce or avoid potentially significant environmental impacts, and to examine a reasonable range of feasible alternatives to the project. The information contained in the EIR is reviewed and considered by the agency's decision-making body prior to its action on the proposed project. The

2.3 CEQA Public Involvement Process

2.3.1 Notice of Preparation

In accordance with Sections 15063 and 15082 of the CEQA Guidelines, the San Francisco Planning Department, as lead agency, prepared a Notice of Preparation (NOP) of an EIR and conducted a public scoping meeting. The NOP was circulated to local, state, and federal agencies and to other interested parties on May 16, 2007, initiating a public comment period that extended through June 18, 2007. This EIR addresses the full range of environmental impacts of the proposed project. The NOP included a preliminary list of the potential environmental impacts in the following resource areas: land use, agriculture, and recreation; employment, population, and housing; aesthetics; biological resources; cultural resources; geology and soils; hydrology, groundwater, and water quality; hazards and hazardous materials; transportation, circulation, and parking; air quality; noise and vibration; utilities and public services; and energy. The NOP provided a general description of the proposed project, locations, and objectives (refer to Appendix A for a copy of the NOP).

2.3.2 Public Scoping Meeting

Pursuant to CEQA Guidelines Section 15083, the San Francisco Planning Department held a public scoping meeting on Tuesday, June 6, 2007, at the Tracy Golf and Country Club, Tracy, California.

A legal notice was placed in the Tracy Press and San Francisco Chronicle informing the general public of the scoping meeting. The purpose of the meeting was to receive public input regarding the scope of the EIR analysis, and attendees were provided an opportunity to submit verbal or written comments.

A Scoping Summary Report was prepared to summarize the public scoping process and the comments received in response to the NOP. This report is included in Appendix A. Fifteen people unrelated to project staff attended the meeting and signed the sign-in sheet, with four of those participants providing oral comments, and two providing written comments on comment cards. A transcript of the scoping meeting and reproductions of the comment cards are included in the Scoping Summary Report.

2.3.3 Public and Agency Comments on the NOP

The comment period on the NOP extended from May 16 through June 18, 2007. Four written comments were received during the public review period, and two additional written comments were received after the public review period. Written and verbal comments were also received at the public scoping meeting. The following provides a summary of the comments received:

Air Quality. Comments were received on whether chlorine would be released into the air as a result of the project. No chlorine gas is emitted currently from the project sites, and the proposed project would not result in any such emissions. Comments were received on dust emissions during construction. Refer to Section 4.9 for a discussion of air quality.

Hazardous Materials. Comments were received about the use of chlorine at the Tesla Portal site. Refer to Section 4.13 for a discussion of hazardous materials including the use of chlorine or other hazardous materials.

Biological Resources. Comments were received on whether the project would affect wetlands. The project would affect an artificial wetland and ephemeral drainage on the Tesla Portal site. Refer to Section 4.6 for a discussion of biological resources.

Traffic and Circulation. Comments were received on the potential effect of the project on traffic near the Tesla Portal site. Refer to Section 4.8 for a discussion of traffic conditions at the project site.

Single comments were received on various topics within the following environmental impact areas: visual quality (refer to Section 4.3), coordination between the WSIP Draft PEIR and the *San Joaquin Regional Water Quality Improvement Project* EIR (refer to Section 2.2 and Appendix B), cultural resources (refer to Section 4.7), cumulative impacts (refer to Section 4.15), energy (refer to Section 4.14), growth inducement (refer to Chapter 6), hydrology and water quality (refer to Section 4.5), noise (refer to Section 4.10), project description (refer to Chapter 3), and water supply (refer to Section 4.5 and Chapter 6).

2.3.4 Draft EIR Public Review

This Draft EIR will undergo a 45-day public review period, and will include a public hearing near the project sites and a public hearing before the San Francisco Planning Commission in San Francisco, to solicit comments from the public and agencies. The public comment period is from August 25 to October 8, 2008. During the public review period, comments on the accuracy and completeness of the information presented herein will be accepted.

This document is being circulated to local, state, and federal agencies and to interested organizations and individuals that may wish to review and comment on the report. Publication of this Draft EIR marks the beginning of a 45-day public review period, during which written comments may be directed to the following address:

San Francisco Planning Department

  20 E. Eaton Avenue
  Tracy, CA 95376-3100

The Draft EIR can also be accessed through the internet at: www.sfgov.org/site/planning/mea

Public Hearings

Public hearings on the Draft EIR to accept written or oral comments are scheduled as follows:

- September 18, 2008 – San Francisco Planning Commission – Room 400, City Hall, 1 Dr. Carlton B. Goodlett Place, San Francisco, beginning at 1:30 p.m. or later (call 558-6422, the week of the hearing for a recorded message giving a more specific time).

- September 16, 2008 – Additional public hearing – Tracy Golf and Country Club, 35200 South Chrisman Road, Tracy, beginning promptly at 6:30 p.m.

2.3.5 Comments and Responses Document and Final EIR

Written and oral comments received in response to the Draft EIR will be addressed in a Comments and Responses document. This document will be released for public review. The Draft EIR and the Comments and Responses will together constitute the Final EIR. The San Francisco Planning Commission will then consider EIR certification (CEQA Guidelines, Section 15090) during a public hearing. Following EIR certification, the SFPUC may proceed to take action on the proposed project. CEQA also requires the adoption of findings prior to approval of a project where a certified EIR identifies significant environmental effects that would be caused by the project (CEQA Guidelines Section 15091 and 15092).

2.3.6 Mitigation Monitoring and Reporting Program

- At the time of project approval, CEQA requires lead agencies to "adopt a reporting and mitigation monitoring program for the changes to the project which it has adopted or made a condition of project approval in order to mitigate or avoid significant effects on the environment" (CEQA, Section 21081.6; CEQA Guidelines, Section 15097). This EIR identifies and presents mitigation measures that would form the basis of such a mitigation monitoring and reporting program. Any measures adopted by the SFPUC as conditions for approval of the project will be included in a Mitigation Monitoring and Reporting Program to ensure compliance.

2.4 Organization of the EIR

This EIR is organized into nine chapters, as discussed below:

Chapter 1, Executive Summary. This chapter presents a summary of the SFPUC's regional water system and the WSIP, and also a summary of the proposed project and the alternatives considered in this EIR. This chapter also summarizes potentially significant environmental impacts and mitigation measures.

Chapter 2, Introduction. This chapter provides project background information and describes the purpose and organization of the EIR, as well as its preparation, review, and certification processes.

Chapter 3, Project Description. This chapter presents the proposed project description, including project objectives, a summary of project components, and describes project construction.

Chapter 4, Environmental Setting and Impacts. This chapter is presented in sections that describe the environmental setting and assess the environmental impacts for each environmental resource area. Each resource area section describes the environmental and regulatory setting, significance criteria, approach to analysis, and presents an analysis of potential environmental impacts.

Chapter 5, Mitigation Measures. This chapter presents the project-specific mitigation measures developed to address each impact considered to be potentially significant.

Chapter 6, Growth Inducement. This chapter presents the growth inducement potential of the proposed project in the context of the WSIP.

Chapter 7, Significant Environmental Effects that Cannot be Avoided if the Proposed Project is Implemented. The chapter presents a summary of significant unavoidable project impacts.

Chapter 8, Significant Irreversible Environmental Changes. This chapter presents a discussion of significant irreversible environmental changes.

Chapter 9, CEQA Alternatives. This chapter describes the alternatives to the proposed project and compares their impacts to those of the proposed project. This chapter also provides a brief description of alternatives that were considered but screened from further analysis.

CHAPTER 3
Project Description

3.1 Project Goals and Objectives

3.1.1 Relation to Water System Improvement Program Goals

The proposed project is part of the San Francisco Public Utilities Commission's (SFPUC's) Water System Improvement Program (WSIP). The WSIP goals and objectives (refer to Table 2-1 in Chapter 2.0, Introduction) were developed based on a planning horizon through 2018. The overall goals of the WSIP for the regional water system are to:

- Maintain high-quality water
- Reduce vulnerability to earthquakes
- Increase water delivery reliability
- Meet customer water supply needs
- Enhance sustainability
- Achieve a cost-effective, fully operational system

The size and design of the individual WSIP facility improvement projects are driven by the WSIP's system performance objectives and would not change as a result of the WSIP's water supply strategy. The originally proposed WSIP included multiple program goals for improving seismic reliability and water delivery reliability, meeting current and future water quality regulations, and meeting water supply reliability goals. Design and capacity of the WSIP facility improvement projects is driven by all four of the WSIP objectives—the need to improve system performance for seismic reliability and water delivery reliability as well as maintaining high water quality standards and meeting water supply goals. All four of these objectives are factored into the decision on how to size the WSIP's individual facilities. Even if the goal of meeting projected increases in water supply demands were dropped from the mix of program objectives, the other program goals would cause the SFPUC to design WSIP facility improvement projects of the same size. All the WSIP facilities are sized to reliably deliver an average annual amount of 265 mgd (and up to 300 mgd) in light of the regional system's needs for seismic and delivery reliability during both drought and non-drought periods, and to meet water quality requirements (SFPUC Resolution No. 08-0200).

The proposed project is primarily proposed to ensure that the SFPUC maintains high-quality water that meets or exceeds regulatory standards for drinking water into the future and, therefore, would contribute to the WSIP's water quality goal. The proposed Tesla Treatment Facility is also consistent with WSIP efforts to reduce the water system's vulnerability to earthquakes.

The WSIP goals and objectives are founded on two fundamental principles pertaining to the existing regional system: (1) maintaining a clean, unfiltered water source from the Hetch Hetchy system; and (2) maintaining a gravity-driven system. The overall treatment strategy of the proposed project assumes that these goals are met.

3.1.2 San Joaquin Regional Water Quality Improvement Project Objectives

The objectives of the proposed *San Joaquin Regional Water Quality Improvement Project* (project) consist of the following:

Tesla Treatment Facility (Tesla Portal Site)

- Replace existing water treatment facilities that are not currently seismically safe with new facilities that are designed to meet current seismic, safety/fire, and building code standards

- Construct new water treatment facilities to meet U.S. Environmental Protection Agency (U.S. EPA) requirements for *Cryptosporidium* reduction/inactivation in drinking water, as required under the U.S. EPA's Long Term-2 Enhanced Surface Water Treatment Rule (LT2ESWTR)

- Improve current water quality management capabilities such as pH control

Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)

- Construct new water treatment facilities to meet U.S. EPA requirements under the Surface Water Treatment Rule (SWTR) for the reduction/inactivation of *Giardia*, as well as assist in meeting LT2ESWTR *Cryptosporidium* requirements to enable delivery of potable water to Lawrence Livermore National Laboratory (LLNL) from the Thomas Shaft of the Coast Range Tunnel

- Continue to provide back-up chlorination capabilities

3.2 Project Location and Setting

The components of the proposed project, as described below in Section 3.3, would be constructed at two separate sites, the Tesla Portal site and the Thomas Shaft site. The following provides a description of the two sites.

3.2.1 Tesla Portal Site

The Tesla Portal site is located about 7.5 miles south of the City of Tracy, in unincorporated southwestern San Joaquin County. The site as a whole is about 52 acres; the proposed project, including construction staging, would occur on about 12 acres of the site.

The primary existing structure at the 52-acre site is the Tesla Portal structure. A steel overflow/surge shaft rises approximately 60 feet from a hillside near the Tesla Portal structure. The oldest buildings at the site are a wood-frame building housing the chlorination facility (the Tesla Portal Hypochlorite Station), a pump house, and a watershed keeper's cottage, all built in 1936. Two valve houses were later added in 1949 and 1963. Three 20,000-gallon water tanks are located on a hillside above the other buildings. Various minor upgrades and improvements have been added at the site over the years, including an improved access road and security gates in 2003.

The existing Tesla Portal Hypochlorite Station, constructed in 1936, originally was a gas chlorine facility and, for a while before World War II, also fed gas ammonia and provided chloramine disinfection. The facility was converted to a Hypochlorite Station in 1989. The facility is a primary disinfection point for the regional water system. At the Tesla Portal Hypochlorite Station, sodium hypochlorite, a liquid form of chlorine, is injected utilizing two tanks outside the facility and four tanks inside the facility, to reduce/inactivate viruses and *Giardia*. No chlorine gas is released during the process. The existing Tesla Portal Hypochlorite Station handles a maximum flowrate of 290 million gallons per day (mgd) and an average flowrate of 220 mgd. It is operated continuously 24 hours per day and requires routine maintenance. Facility operations are controlled via the SFPUC's Supervisory Control and Data Acquisition (SCADA) System.

There is an existing grazing lease at Tesla Portal that allows cattle grazing on the site.

The proposed new structures at this site (refer to Section 3.5) would be constructed on 3 acres of the site characterized as undeveloped grassland with gently rolling hills, generally northeast of existing structures. Outside of the boundaries of the Tesla Portal site, the areas immediately north, west, and south of the site are occupied by ranching operations on private property. Roughly 0.5 miles to the east lies the community of Chrisman a rural residential neighborhood within the unincorporated Tracy Planning Area (San Joaquin County, 1992) consisting of approximately 36 rural residential parcels. The closest residential structure to Tesla Portal is located approximately 2,500 feet to the southeast of the project area, off West Vernalis Road. There are several uninhabited ranch structures located approximately 750 feet west of the project area (refer to Figure 4.3-1a).

Tesla Portal contains a 0.308-acre artificial wetland area which, during site visits in fall 2006, was observed to have standing water and emergent vegetation (refer to Section 4.6, Biological Resources, for further discussion of the wetland area). The primary water source for this area is runoff from sampling points discharged through a pipe at the existing Tesla Portal Hypochlorite Station. This area is approximately 100 feet from the existing access road. In addition, the Tesla Portal site contains an ephemeral drainage averaging 1.5 feet in width within the project area and approximately 1,420 feet in length that flows from southwest to the northeast across the southern portion of the site. An ephemeral drainage is a stream, creek, wash or gully that has seasonal, infrequent water flow. The ephemeral drainage was dry during site visits in winter and fall 2007. The primary hydrologic sources for the ephemeral drainage include direct precipitation and surface runoff from the surrounding hills. A spillway associated with the operations at the Tesla Portal site also leads to the ephemeral drainage, and there is evidence immediately below the spillway indicating that some flow enters the ephemeral drainage from the spillway.

3.2.2 Thomas Shaft Site

The Thomas Shaft site is located about 4.4 miles southwest of the Tesla Portal, and about seven miles southwest of the City of Tracy in unincorporated southwestern San Joaquin County. The Thomas Shaft site as a whole is about 28 acres; the proposed project would occur on the developed portion of the site, which totals approximately one acre. Access to the developed portion of the site is via Thomas Shaft Road, an existing private road that starts at Corral Hollow

Road about 1.5 miles north of the site, which is shared with an adjacent property owner at its northern end.

In the developed portion of the Thomas Shaft site, a tunnel and access shaft were constructed when the Coast Range Tunnel was first installed in the area. The site also contains a backup chlorination facility, constructed in 1995 and modernized and upgraded in 2001, to chlorinate Hetch Hetchy water if adequate chlorination does not occur at the Tesla Portal Hypochlorite Station. The facility can be operated manually or using the SCADA system. Components of the facility include a chemical receiving and storage facility, a chemical unloading area, and a control and power supply area. The chemical receiving and storage facility contains three 6,000-gallon sodium hypochlorite tanks, several pumps, and associated piping and sensors. The facility also has water quality analyzers that sample water for quality control.

The area immediately surrounding Thomas Shaft on all sides is hilly grassland, with occasional oak trees (refer to Figure 4.3-1b). Cattle grazing occurs in the general vicinity on private property. No jurisdictional wetlands are present in the vicinity of the existing chlorination facility on the Thomas Shaft site; however, there are approximately 0.251 acres of unvegetated Waters of the U.S. and approximately 0.188 acres of jurisdictional wetlands located adjacent to Thomas Shaft Road near its intersection with Corral Hollow Road (CCSF Planning Department, 2007). A jurisdictional wetland is a wetland feature that meets the U.S. Army Corps of Engineers' and/or the Regional Water Quality Control Board's definition of a wetland and, therefore, would be protected and regulated by the respective agency. Aerial photographs show a rural residence about 1.25 miles to the northeast of the site. The entrance to LLNL Site 300 is located near the intersection of Thomas Shaft Road and Corral Hollow Road, about 1.5 miles to the north. LLNL Site 300 contains a variety of office buildings and other structures.

LLNL is an existing retail customer of the SFPUC. LLNL receives water through Mocho Shaft, located west of the Thomas Shaft, for Site 200 and, in the past received water from Thomas Shaft for Site 300. Due to current water quality regulations, LLNL does not presently receive water from Thomas Shaft but continues to receive water from Mocho Shaft.

- The SFPUC prepared demand projections for its retail service area, which includes LLNL, in November 2004. The demand projections were based on water deliveries in fiscal year (FY) 2000/01. Because LLNL's average annual water deliveries can vary substantially from year-to-year, the SFPUC used an average from FY 1996/97 to FY 2000/01 to develop their base year average annual water delivery for the demand projection analysis (SFPUC, 2004a).

- LLNL's annual average demand is estimated at 0.8 mgd and the future projected demand is estimated to remain at this level through 2030 (SFPUC, 2004a). Over the last 10 years (FY 1997/98 to FY 2006/07), LLNL's average annual demand has ranged from a low of 0.41 mgd to a high of 0.92 mgd, with a 10-year average of 0.68 mgd (SFPUC, 2004a).

SFPUC and LLNL have a contract, executed in 1960 and amended in 1987, under which SFPUC is to supply water to LLNL Site 300 after treatment at Thomas Shaft. To assist in water delivery, LLNL installed a 10-inch water line and pumps in 1995 across Thomas Shaft Road from the chlorination facility. However, because Thomas Shaft cannot meet SWTR standards for the

reduction/inactivation of *Giardia*, SFPUC cannot deliver water to Site 300 currently. The current water supply for Site 300 comes from onsite wells[1] serving a population of about 250 workers and visitors.

3.3 Proposed Project Components

The proposed *San Joaquin Regional Water Quality Improvement Project* consists of the components identified in Table 3-1, Summary of Project Components.

TABLE 3-1

SUMMARY OF PROJECT COMPONENTS

Project Component	Tesla Treatment Facility (Tesla Portal Site)	Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)
New Facilities	• Chemical Process Building (14,000 square feet) would include: – Three 16,000-gallon sodium hypochlorite tanks – Two 10,000-gallon fluoride tanks • Office/Control Building (3,500 square feet) • UV Building (20,000 square feet) would include: – 12 UV reactors (10 active, two standby) operating 24 hours/day – Below-grade piping vaults – Two 3,000-gallon food-grade acid tanks • Two diesel standby generators (1,500 kW each maximum) • Two 15,000-gallon above ground diesel fuel tanks • Two 12,500-gallon CO_2 tanks with control panels and injection water pumps • Analyzer shed (100 square feet) with water quality sampling equipment • Two valve vaults (approximately 26' × 36' × 16' deep) • Two valve houses (approximately 26' × 36' × 12' high) • 90,000-gallon containment basin lined with rip rap for blow off water (50' × 50' × 5' deep) • New septic tank and leach field • Microwave tower up to 100 feet in height	• Two UV reactors (one active, one standby) installed in existing Chlorination Facility building, operating five hours/day • Prefabricated building within fenced area atop Thomas Shaft (approximately 18' × 20' × 10' high) • Percolation water tank (2,500-gallon concrete tank with crushed rock bottom) for process water

1 The wells are owned by the Department of Energy/National Nuclear Security Administration, and operated by Lawrence Livermore National Security, LLC (LLNS), the contractor in charge of LLNL. LLNS is a limited liability corporation made up of Bechtel National, Inc., the University of California, BWX Technologies, Inc., and the Washington Group International, Inc. The team also includes Battelle Memorial Institute, four small business subcontractors, and Texas A&M University.

TABLE 3-1
SUMMARY OF PROJECT COMPONENTS

Project Component	Tesla Treatment Facility (Tesla Portal Site)	Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)
Existing Facility Modifications	• Steel or concrete enclosure placed around the Portal and covered with soil backfill • New and replacement fencing 3,000 feet in length, 8-foot high	• Replace two existing 100 hp pumps with two approximately 30 hp pumps (one active, one standby)
Roadway Improvements	• 40,000 square feet of new paved areas – New paved 20-foot wide loop road (1,500 feet long) – New asphalt surfacing and widen existing access road from 17 to 20 feet – New parking areas • Remove portion of existing access road (approximately 700 feet)	None
Water Discharges	• Blow off for grit removal (10,000 gallons each blow off, approximately three times/ month)	• Process water (approximately 500 gallons/day to percolation tank)
Trenching	• 144" pipeline (1,200 feet) • 84" pipeline (300 feet) • 48" pipeline (600 feet)	• 12" pipeline (150' × 3' × 3' trench)
Outdoor Lighting	• Along building exterior walls and parking areas	None
Utility Upgrades	• New transformer	None
Operational Changes	• Increased staff from three FTE to five FTE	• Minor increased maintenance activities related to pumps and UV lamp replacement
Staging Area	• 9-acre area located onsite	• Located onsite on paved area adjacent to Chlorination Facility building
Construction Schedule	• January 2009 – January 2011 (24 months) • After construction, there would be a 12-month commissioning (startup testing) period including UV tests by State regulators	• July 2009 – December 2009 (6 months)

The tie-in of new facilities described in this table would occur during the regularly scheduled Hetch Hetchy shutdown in January to February. No interruption to SFPUC customers would occur, as they would continue to be served by other system sources.

The proposed project would not require any land acquisition.

3.3.1 Tesla Treatment Facility (Tesla Portal Site)

The existing building at the Tesla Portal site that contains the Tesla Portal Hypochlorite Station does not meet current seismic, safety/fire, and building code standards. The proposed Tesla Treatment Facility would replace this building with a new 14,000-square-foot Chemical Process Building approximately 32 feet in height containing disinfection and related equipment, and supporting facilities and infrastructure. The building would contain three 16,000-gallon sodium hypochlorite tanks, two 10,000-gallon fluoride tanks, two 12,500-gallon carbon dioxide (CO_2)

tanks, a chemical spill control system, electrical room, shop/storage room, and chemical feed equipment, including metering pumps, transfer pumps, piping and instrumentation (e.g., pressure gauges, flow meters, and tank level indicators).

- *Giardia* inactivation is currently accomplished through the addition of sodium hypochlorite (chlorine) to the regional water supply at the Tesla Disinfection Facility or at Thomas Shaft, which provides adequate contact time for the inactivation of *Giardia*. To provide adequate *Giardia* disinfection to LLNL Site 300, additional ultraviolet (UV) facilities would be installed at Thomas Shaft (see Section 3.2). Chlorine would be fed from the Chemical Process Building and injected into the out flow manifolds. Although the location of the chlorination function at the site would change, the chlorine injection process itself would be essentially unchanged. In addition, to lower the pH of the water, fluoride and CO_2 would be added to improve current water quality management capabilities.

The functions of the Chemical Process Building would continue to be monitored and operated manually or via SCADA. The existing building that contains the Tesla Portal Hypochlorite Station would no longer be occupied or used to house treatment processes but would be maintained to prevent deterioration, and may be used to store equipment.

In addition to the Chemical Process Building, a new 3,500-square-foot Office/Control Building approximately 12 feet in height is proposed. The Office/Control Building would contain offices, control room, process room, laboratory, restrooms, lockers, shower, and a multipurpose room. Both the Chemical Process Building and Office/Control Building would have heating, ventilation, and air conditioning systems as well as fire protection systems, using water sprinklers, and dry chemical systems.

At the Tesla Portal site, a new ultraviolet (UV) disinfection facility is also proposed that would allow the SFPUC to achieve the high level of disinfection to inactivate *Cryptosporidium* to levels mandated under LT2ESWTR by running Hetch Hetchy water past arrays of UV lamps. The proposed UV Building would be up to 20,000 square feet and approximately 32 feet in height above ground, and would contain 12 UV reactors (10 active and two standby) each containing UV lamp arrays and various sensors, on a floor recessed approximately 14 feet below grade. In addition, the building would contain below-grade piping vaults and two 3,000-gallon food-grade acid tanks. Two diesel standby generators are proposed adjacent to the UV Building and two 15,000-gallon above ground diesel fuel tanks are proposed adjacent to the Chemical Process Building.

The Tesla Treatment Facility is being designed to withstand seismic events, and for "zero failure" by providing both backup UV reactors and backup generators in the event of a power outage. In addition, power supply at the site is being upgraded to improve reliability and to minimize the potential for power outages or UV reactor down time, thus minimizing the potential for unplanned discharges of water that do not meet water quality requirements. If unplanned discharges were to occur, the water would be discharged within the Sunol Valley, as is currently the case, to the San Antonio Reservoir, to the Sunol Valley Water Treatment Plant or to San Antonio Creek via the existing San Antonio Pipeline. In addition, if implemented, the proposed

WSIP Alameda Siphons Seismic Reliability Upgrade project would provide an additional discharge point to an adjacent quarry pit.

The tie-in of the proposed UV Building to San Joaquin Pipeline (SJPL) Nos. 1, 2 and 3 would require cutting into all three pipelines and connecting a new manifold that would combine the

flows and redirect the water through an array of UV reactors inside the building, into a new outlet manifold and back into the SJPLs. All tie-ins would occur upstream of the existing valve-houses. Construction of both the upstream and downstream manifolds would require cutting into the pipe in two places (one upstream, one downstream) and removing about 300 feet total of each pipeline. The new manifolds would be constructed in the place vacated by the demolished pipe. In addition, the upstream manifold would incorporate a line-sized isolation valve in each pipeline. A connection to the manifold and an isolation valve would also be constructed to accommodate future connection of a fourth San Joaquin pipeline.[2] This connection would be located approximately 900 feet east of an existing connection point on the Coast Range tunnel manifold that was originally provided for this purpose, thus this connection point would be relocated to accommodate the proposed Tesla Treatment Facility. Approximately 400 feet of each existing SJPL would be capped and remain in place between the upstream and downstream manifolds. All new and existing segments under the proposed project would be located below grade, or enclosed in structures.

The proposed Tesla Treatment Facility would be controlled independently of the operation of the SJPL valves. The facility design criteria is listed at 315 mgd to account for design limitations and to allow the facility to provide reliable disinfection for a future flowrate of 313 mgd, consistent with the proposed water supply option identified in the WSIP.

The project would also replace and upgrade the existing communication system at the Tesla Hypochlorite Station with an improved system, and provide the foundation infrastructure to integrate the new Tesla Treatment Facility communication system with the existing Sunol Valley Water Treatment Plant and the pipelines control center at Moccasin. To facilitate the communication improvements, a microwave tower would be installed adjacent to the three existing water tanks located on the hillside above the other existing structures on the site. The proposed lattice tower would be up to 100 feet in height with two 8-foot-diameter microwave dishes mounted at the top of the tower, one directed toward the Livermore Hills (approximately 320 degrees northwest) and the other directed toward Oakdale (Warnerville Road Switchyard approximately 60 degrees northeast). Other smaller antennas would also be mounted at the top of the tower. The tower would be constructed of galvanized steel, and the microwave dishes, antennas or other equipment on the tower would be painted gray to reduce visibility. The tower would be installed on a concrete foundation that would be a maximum of 30 feet by 30 feet. Access to the tower would be via an existing unpaved road. An underground electrical line would be required from the tower to a new transformer adjacent to the UV Building.

Additional improvements proposed at the Tesla Portal site consist of a new steel or concrete enclosure around the Tesla Portal that would be covered with soil backfill, installation of new paved areas (detailed in Table 3-1), a 90,000-gallon containment basin lined with rip rap to capture released water for grit removal and periodic maintenance (three times per month), and a 100-square-foot analyzer shed approximately 10 feet in height for water quality sampling equipment. Water discharged to the proposed containment basin would be raw water (no

[2] A Notice of Preparation for the proposed SJPL System Project (Case No. 2007.0118E) was published by the San Francisco Planning Department in spring 2007, and the preparation of a Draft EIR is underway.

chlorine). In addition to the underground piping (listed in Table 3-1), other small diameter piping would be laid for process sample lines.

Security improvements are also proposed, including approximately 3,000 feet of new and replacement fencing, 8 feet in height surrounding the proposed developed area where the new treatment facilities would be located, and other security features (e.g., controlled gate and entry system, and intrusion detection system). Finally, the project proposes an outdoor lighting system designed to utilize a minimum number of fixtures based on the recommendations of the Illumination Engineering Society of North America and the guidelines of California Code of Regulations Title 24. Pole mounted high-pressure sodium or metal halide lamps would be used for outdoor areas such as roadways and parking. Along building exterior walls, compact fluorescent or low-wattage metal halide lamp fixtures would be used. During tie-ins or at other times, as needed, some weekend or nighttime construction work may be necessary. If nighttime construction work is conducted, temporary additional nighttime lighting would be needed.

Figure 3-1 shows the location of the proposed Chemical Process Building, Office/Control Building, UV Building, and additional project features. The new facilities, including buildings and paved areas, would be constructed northeast of existing structures at Tesla Portal, on an approximately three-acre site that currently is undeveloped grassland. An additional approximately nine-acre undeveloped grassland area extending on both sides of the entrance road would be used for construction staging.

Pacific Gas and Electric Company (PG&E) currently provides electrical service to the Tesla Portal site. Proposed facilities at the site would increase the consumption of electricity and would require a new electrical transformer (8 feet by 10 feet by 9 feet in height), which is proposed adjacent to the UV Building. An above ground power line would extend from the existing power pole to the new transformer, and then the power line would be undergrounded from the transformer to the new buildings. Natural gas service would not be required for the new facilities.

Telephone service would be extended to new buildings from existing connections at the Tesla Portal site. Drinking water would continue to be obtained from the existing SFPUC system serving the site. To handle sewage and graywater, a new septic tank and leachfield would be installed to the east of the new buildings. Storm water would be collected and directed away from the new structures and released in a soakaway system that would be located near the leachfield.

The primary water source for the artificial wetland described above in Section 3.2 (runoff from sampling points at the existing Tesla Portal Hypochlorite Station) would be discontinued. However, surface runoff may continue to be directed into the artificial wetland.

The proposed Chemical Process Building, Office/Control Building, and UV Building would be constructed with concrete walls and foundations. Each of these buildings would require that existing vegetation in the vicinity be cleared and the sites graded. Approximately 3.2 acres would be graded in total at this site. The maximum excavation depth would be 20 feet. Excavated material would be used as fill for site grading. Due to the relatively flat nature of the site, it is expected that the cut and fill volumes would be balanced to minimize the import or export of soils. The extent of fill activities would be within the 3.2-acres that would be graded, except areas

that would be excavated for new pipeline or the electrical line for the microwave tower that would be outside the graded area. The excavated material from these areas would be used to refill the trenches. Thus, truck traffic would be relatively limited. Except for brief periods when concrete would be poured, approximately 25 to 30 truck round-trips per day would occur during construction, including worker commuter truck trips (refer to Section 4.8, Traffic, Transportation and Circulation). Current staffing levels are approximately three full-time equivalent (FTE) personnel on site. The proposed project would add two FTEs. The additional staff would be onsite intermittently, as needed.

The existing disinfection function of Tesla Portal would not be interrupted during construction as a result of the project. The tie-in of new facilities would occur during the scheduled Hetch Hetchy shutdown in January to February. No interruption in service to SFPUC customers would occur as they would continue to be served by other system sources.

3.3.2 Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)

SFPUC has a contractual agreement with LLNL to deliver drinking water to LLNL Site 300. Presently, SFPUC cannot supply LLNL Site 300 because water from Thomas Shaft does not meet SWTR standards for *Giardia* reduction/inactivation. To meet SWTR requirements, and assist in meeting LT2ESWTR requirements, the treatment facility serving LLNL Site 300 at Thomas Shaft would be upgraded by installation of a UV disinfection system. The UV system would be installed in the existing Chlorination Facility building at the site, and consist of two UV reactors, each containing several UV lamp arrays, as well as a power supply and control panel. Refer to Figure 3-2, Thomas Shaft Site Plan. The Lawrence Livermore Water Quality Improvements are being designed for a 0.165 mgd capacity. The proposed project would allow LLNL to take up to 0.165 mgd of their annual average demand of 0.8 mgd from Thomas Shaft, and continue to receive the remainder of the water from Mocho Shaft.

A 2,500-gallon concrete percolation tank with crushed rock bottom would be installed for process water discharge at the Thomas Shaft site. The water discharged to the tank would have chlorine residual from chlorination that occurs at the Tesla Portal site. The tank would not be sealed at the bottom, and would be filled with 12 to 18 inches of crushed rock. Two 12-inch diameter polyvinyl chloride (PVC) pipes would be installed 15 feet deep to allow water to reach sand to facilitate percolation. The tank would be the discharge point for process water used for sampling chlorine residual, pH and turbidity of water at Thomas Shaft before and after UV disinfection, and for chlorinated process water from existing Thomas Shaft Chlorination Facility sampling instruments.

- Other improvements proposed at the Thomas Shaft site include installation of a 360-square-foot prefabricated structure 10 feet in height within the fenced area atop Thomas Shaft and replacing two existing 100 horse power (hp) pumps with two 30 hp pumps (one active and one standby). An approximately 150 foot by 3 foot by 3 foot trench would be excavated from the existing Chlorination Facility building to the Thomas Shaft and to the percolation tank (as shown on Figure 3-2). Prior to commencement of this project, fencing will be installed as part of another

project (Thomas Shaft Roadway Improvement Project, SFPUC Resolution No. 08-0061) and will remain installed around the steam engine foundation and bucket assembly; this fence will avoid potential inadvertent physical impacts or damage to the resource that could occur during project construction.

Not To Scale

SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT EIR

Thomas Shaft Site Plan

Figure 3-2

The cut and fill volumes would be minimal (only from some minor trenching) and can be roughly balanced on-site. The import or export of soils is not expected. Approximately five truck round-trips per day would occur during construction, including worker commuter truck trips (except for a brief period when concrete would be poured for the small prefabricated building foundation). Existing operations, which are minimal, would not be interrupted as a result of the project. No new utility service from offsite sources would be required.

3.4 Project Construction

3.4.1 SFPUC Standard Construction Measures

SFPUC has established standard construction measures that are implemented as part of all SFPUC projects, including the project that is the subject of this EIR (SFPUC, 2007c). The objective of these measures is to minimize potential disruption of surrounding neighborhoods during construction and to reduce impacts on existing resources to the extent feasible. Each SFPUC project manager, environmental project manager, and contract manager would ensure that projects involving construction work contain uniform provisions to address these issues. To that end, each construction contract or project must include the following standard construction measures in the contract or project implementation procedures, as appropriate. The measures would apply to work that would require any environmental review and is conducted by SFPUC staff or by outside contractors under contract with the SFPUC. The standard construction measures consist of the following provisions:

1. *Neighborhood Notice*: The SFPUC will provide reasonable advance notification to the businesses, owners and residents of adjacent areas potentially affected by the WSIP projects about the nature, extent and duration of construction activities. Interim updates should be provided to such neighbors to inform them of the status of the construction.

   Where schools would be affected, the SFPUC will coordinate with school facility managers to schedule construction for time periods with the least impact on school activities and facilities to ensure student safety and to minimize disruption to educational and recreational uses of the school property.

2. *Seismic and Geotechnical Studies*: Projects will incorporate review of existing information and, if necessary, new engineering investigations to provide relevant geotechnical information about the particular site and project, including a characterization of the soils at the site, and the potential for subsidence and other ground failure. Construction will address any recommendations by such geotechnical reports to ensure seismic stability and reliability of the proposed project. All SFPUC projects must be designed for seismic reliability and minimum potential water loss and property damage. All components of the water system improvement program must be designed to continue water service during a major earthquake.

3. *On-Site Air and Water Quality Measures During Construction*: All construction contractors must take measures to minimize fugitive dust and dirt emissions resulting from the construction, and implement measures to minimize any construction effects on

local air and water quality, including a local storm drain system or watercourse. These measures could include preparation of a Stormwater Pollution Prevention Plan (SWPPP), if required by the relevant Regional Water Quality Control Board. At a minimum, construction contractors should prepare an erosion and sediment control plan and undertake the following measures, as applicable, to minimize any adverse effects:

- Erosion and sedimentation controls tailored to the site and project
- Dust control plan
- Placement of straw rolls around each of the nearby stormwater inlets
- Preservation of existing vegetation
- Installation of silt fences
- Use of wind erosion control (e.g., geotextile or plastic covers on stockpiled soil)
- Sweeping of nearby streets
- Stabilization of site ingress/egress locations to minimize erosion, and/or
- Spraying the disturbed areas of the site, or any stockpiled soil, with water to minimize fugitive dust emissions

4. *Groundwater*: If groundwater is encountered during any excavation activities, the construction contractor shall prepare a dewatering plan so that water is discharged to the stormwater system in compliance with the local standards and discharge permit requirements.

5. *Traffic*: Each contractor shall prepare a traffic control plan which will minimize the impacts on traffic and on-street parking on any streets affected by construction of the proposed project. As appropriate, SFPUC or the contractor will consult with local traffic and transit agencies.

6. *Noise*: The contractor will comply with local noise ordinances regulating construction noise to the extent feasible, and will undertake efforts to minimize any noise disruption to nearby neighbors and sensitive receptors during construction.

7. *Hazardous Materials*: Appropriate measures will be implemented to characterize and dispose of hazardous materials should they be encountered during excavation and construction. Contract specifications will mandate full compliance with all applicable local, state and federal regulations related to the identification, transportation and disposal of hazardous materials/soils. As necessary, a spill prevention and countermeasure plan will be prepared.

A qualified environmental professional will conduct any necessary site assessment. The site assessment would include a regulatory database review to identify permitted hazardous materials and environmental cases in the vicinity of each project no more than three months before construction, and a review of appropriate standard information sources to determine the potential for soil or groundwater contamination to occur. Follow-up sampling would be conducted as necessary to characterize soil and groundwater quality prior to construction and, if needed, site investigations or remedial activities would be performed in accordance with applicable laws. The environmental professional would prepare a report documenting the activities performed, summarize the results and make recommendations for appropriate handling of any contaminated materials during construction. A contingency plan would also be prepared identifying measures to be taken should unanticipated contamination be identified during construction. Construction contractors will conduct asbestos and lead abatement in accordance with established regulations.

8. *Biological Resources*: As an initial matter, SFPUC will have a qualified professional screen the project site and area to determine whether biological resources may be affected by construction activities. In the event further investigation is necessary, the SFPUC will comply with all requirements for investigation, analysis and protection of biological resources.

   A qualified biologist must conduct any required biological screening survey. The biologist will review standard information sources to determine special status species with the potential to occur on the project site. The biologist would carry out a site survey by walking or driving over the project site, as appropriate, to note the general resources and whether any habitat for special-status species is present. The biologist would then document the survey with a brief letter report or memo, setting forth the date of the visit, whether habitat for special-status species is present, providing a map or description showing where sensitive areas exist within the site, and identifying any appropriate avoidance measures.

9. *Cultural Resources*: As an initial matter, SFPUC project managers will screen the project site and area to determine whether cultural resources, including archaeological and other historical resources, may be affected by construction activities. In the event further investigation is necessary, the SFPUC will comply with all requirements for investigation, analysis and protection of cultural resources.

   Any screening for cultural resources would include screening for archaeological, paleontological and historic resources. For projects requiring excavation, deep grading, well drilling or tunneling into geologic material at sites identified as having high potential for encountering paleontological resources, a state-registered professional geologist or qualified professional paleontologist will conduct a site-specific evaluation of the paleontological sensitivity. The assessment will include a report of findings for the SFPUC.

A qualified archaeologist, historian or paleontologist will conduct all cultural resources survey and screening work. Screening surveys for cultural resources would include a cultural resources records search to be conducted at the appropriate office member of the California Historical Resources Information System. A field survey will be conducted if determined necessary after the cultural resources records search. Any impacts on identified cultural resources will be avoided to the extent feasible.

Any initial historic resource screening will identify historic resources on the project site as well as adjacent to the project site.

It is possible that project work may affect accidentally discovered buried or submerged cultural resources. Any contractor must distribute the Planning Department archaeological resource "ALERT" sheet to any person involved in soil-disturbing activities. If there is any indication of an archaeological or a paleontological resource during the soils disturbing activity of the project, the contractor shall immediately suspend any soils disturbing activities in the area and notify the SFPUC of such discovery. The SFPUC will then work with the Planning Department's Environmental Review Officer to determine what additional measures should be implemented, based on reports from a qualified archaeological or paleontological consultant.

10. *Project Site*: The SFPUC will conduct construction activities on SFPUC-owned lands to the extent feasible and minimize the need for use of non-SFPUC-owned land during construction. In cases where construction easement or staging areas are needed on non-SFPUC land, the SFPUC will restore these areas to their prior condition so that the owner may return them to their prior use, unless otherwise arranged with the property owner.

    The site will be maintained to be clean and orderly. Construction staging areas will be sited away from public view where possible. Nighttime lighting will be directed away from residential areas.

    Upon project completion, the construction contractor will return the SFPUC project site to its general condition before construction, including re-grading of the site and re-vegetation of disturbed areas.

3.4.2 Greenhouse Gas Reduction Actions

In addition to the Standard Construction Measures listed above, the SFPUC is committed to the following greenhouse gas (GHG) reduction actions as part of the WSIP. The following actions would be part of the project:

A. The SFPUC will include the first two following measures in contractor specifications and implement the third measure during project planning and design, which in addition to having other environmental benefits, would also help reduce GHG emissions. Some of these measures are part of the California Air Resources Board's (CARB) "Early Action Measures" (refer to Section 4.9, Air Quality).

1. The SFPUC will require that all contractors maintain tire inflation to the manufacturers' inflation specifications.

2. The SFPUC will implement a construction worker education program.

3. Projects that include construction of new buildings will consult with the SFPUC Power Enterprise's Energy Efficiency Group to incorporate all applicable energy efficiency measures into project design. Projects with building components will attempt to maximize energy efficiency by exceeding Title 24 minimum requirements by at least 5 percent. Projects with building components will attempt to meet or exceed LEED Silver certification as required by the City's Green Building Ordinance.

- B. This EIR also includes mitigation measures to help reduce GHG emissions. They include exhaust controls (Mitigation Measure 4.9-1b) and energy efficiency measures (Mitigation Measure 4.14-1). In addition, CARB regulations (Title 13 of the California Code of Regulations, Sections 2480 and 2485), which limit idling of diesel-fueled commercial motor vehicles, would help to limit GHG emissions associated with project construction vehicles.

3.4.3 Construction Labor Force

At the Tesla Portal site, the construction labor force would include eight field management and office staff and an average of approximately 30 field construction workers per month (field construction workers could range from 23 and 61 with an average of approximately 30 per month). Approximately six to 12 workers, including management staff and field construction workers are anticipated at the Thomas Shaft site.

3.4.4 Construction Activity

Apart from truck shipments of construction materials, construction activities for the proposed project would be confined to the proposed site locations and immediate vicinities. The general types of proposed modifications to the treatment facilities at the Tesla Portal and Thomas Shaft sites include:

- Process improvements and additions
- Hydraulic system improvements
- Structural/seismic improvements
- Instrumentation and controls improvements
- Electrical and power system improvements
- Site grading, paving, and drainage

Construction associated with the proposed facilities would be phased so that system operations would not be interrupted during construction. Construction activities anticipated for the Tesla Treatment Facility under the proposed project include ground clearing, excavation, grading, trenching for new pipeline segments, construction of proposed buildings, paving of roadways and parking areas, and installation of equipment. At the Tesla Portal site, nighttime lighting of the construction staging and development areas is proposed to provide security during construction. For the Lawrence Livermore Water Quality Improvements, construction activities would include minor grading and excavation, trenching for new pipeline, and installation of prefabricated building and equipment. Table 3-2, Construction Equipment, shows the types of equipment that would be used at each site.

TABLE 3-2
CONSTRUCTION EQUIPMENT

Equipment Type	Tesla Treatment Facility	Lawrence Livermore Water Quality Improvements
Air Compressor	x	
Backhoe	x	x
Baker Tank	x	
Bulldozer	x	x
Compactor	x	x
Concrete mixer	x	
Concrete pump	x	
Concrete vibrator	x	
Crane, derrick	x	
Crane, mobile	x	x
Dewatering Pump	x	
Excavator	x	x
Generator	x	x
Grader	x	x
Loader	x	x
Paver	x	
Pneumatic tools (e.g., jackhammer, impact wrench)	x	x
Scarifier	x	
Scraper	x	
Ventilation Fan	x	
Trucks	x	x
Welding Equipment	x	x

Access to the Tesla Portal site for construction vehicles and workers would be via I-580, West Vernalis Road and the existing paved road onsite. For the Thomas Shaft site, construction access would be via I-580, Corral Hollow Road and Thomas Shaft Road.

3.5 Project Construction Schedules

Construction at the Tesla Portal site is anticipated to start in January 2009, and last approximately 24 months. After construction, there would be a 12-month commissioning (startup testing) period including UV tests by State regulators.

Construction at the Thomas Shaft site is anticipated to start in July 2009, and last for approximately six months.

Construction at both sites generally would be conducted on weekdays from 7:00 am to 5:00 pm; however, work may occur occasionally on weekends, and could occur 24 hours a day, seven days a week at the Tesla Portal site during tie-in of the new facilities during the regularly scheduled Hetch Hetchy shutdown for approximately 36 days in January to February.

3.6 Water Quality Regulatory Requirements

3.6.1 Safe Drinking Water Act

The water quality regulations governing the regional water system are associated with the federal and California Safe Drinking Water regulations. The federal Safe Drinking Water Act, passed in 1974 and amended in 1986 and 1996, is the nation's major law regulating drinking water quality and is implemented by the U.S. EPA. The act authorizes the U.S. EPA to set national health-based standards for drinking water and requires many actions to protect drinking water and its sources, including rivers, lakes, reservoirs, springs, and groundwater wells. In addition to source water protection, the act also provides for treatment, monitoring, sampling, analytical methods, reporting and public information requirements. Implementation and enforcement of this act has been delegated to the states. In California, the Safe Drinking Water Act is under the jurisdiction of the California Department of Health Services, Division of Drinking Water and Environmental Management. Drinking water regulations are set forth in the California Code of Regulations, Title 22 and Title 17.

The amended federal Safe Drinking Water Act established phases of regulation and a number of regulatory deadlines to address drinking water requirements. This amended act is being implemented through subsidiary rules for regulation of specific contaminants or for monitoring or treatment requirements. The major U.S. EPA subsidiary rules are listed below:

- Surface Water Treatment Rule
- Interim Enhanced Surface Water Treatment Rule
- Total Coliform Rule
- Stage 1 Disinfectants and Disinfection Byproducts Rule
- Long Term 1 Enhanced Surface Water Treatment Rule
- Stage 2 Disinfectants and Disinfection Byproducts Rule

- Long Term 2 Enhanced Surface Water Treatment Rule
- Variances and Exemptions Rule
- Lead and Copper Rule
- Radionuclides Rule
- Filter Backwash Recycling Rule
- Arsenic Rule
- Public Notification Rule

3.6.2 Surface Water Treatment Rule

In 1991, the U.S.EPA adopted the Surface Water Treatment Rule, which included water quality provisions for unfiltered systems, referred to as 'filtration avoidance.' In 1993, the SFPUC applied for the ability to comply with federal filtration avoidance regulations; the California Department of Health Services (DHS) reviewed and approved this application, and forwarded their recommendation to the U.S. EPA that the Hetch Hetchy supply be approved as an unfiltered source that meets all criteria in the federal statute for filtration avoidance. The U.S. EPA also approved this application in 1993. In 1998, the State added filtration avoidance provisions to Title 22 of the California Code of Regulation, under which the Hetch Hetchy supply is currently regulated. In 2000, the SFPUC adopted resolution number 00-0277, reaffirming its policy to maintain the 'filtration avoidance' status for Hetch Hetchy water and directing its staff to prepare and submit operating fund and capital project budget requests which are consistent with proactive maintenance of 'filtration avoidance.'

Water from Hetch Hetchy Reservoir can be delivered to SFPUC customers without filtration, provided that it meets the filtration avoidance requirements outlined in the Surface Water Treatment Rule. These requirements include meeting source water quality standards, disinfection criteria, and site-specific criteria. In the Hetch Hetchy system, the Tesla Portal facility is the compliance point for some pathogens and turbidity, and Alameda East Portal is the disinfection compliance point. The SFPUC conducts extensive routine water quality monitoring and watershed protection activities, and submits a monthly report to the DHS to fulfill the filtration avoidance requirements. The report indicates coliform and turbidity levels and excursions, compliance with disinfection requirements, compliance with Total Coliform Rule, quarterly disinfection byproduct levels, operability of disinfection equipment, watershed control activities, and any detected outbreaks of waterborne disease. In addition, the SFPUC submits an Annual Watershed Sanitary Survey Report summarizing compliance with watershed control program requirements. Since 1993, these activities have demonstrated that without filtration, the water from Hetch Hetchy Reservoir consistently meets or exceeds all water quality standards, indicating a high level of public health protection for regional system customers. Water from Lake Eleanor, Cherry Reservoir, and reservoirs in the Alameda and Peninsula watersheds requires filtration at

either the Sunol Valley or Harry Tracy Water Treatment Plants before it can be delivered to customers.

3.7 Approvals and Permits Required

The City and County of San Francisco Planning Department is the CEQA Lead Agency for the proposed project, and the certification of the Final EIR by the San Francisco Planning Commission would be a required approval.

The SFPUC would consider the certified Final EIR prior to consideration of approval of the proposed project and, if approved, the SFPUC would adopt CEQA findings and a Mitigation Monitoring and Reporting Program.

The San Francisco Board of Supervisors would consider appeals of EIR certification by the San Francisco Planning Commission. The San Francisco Board of Supervisors would also appropriate funding for implementation of the proposed project, including general obligation bond monies and annual budget appropriations. In addition to CEQA, the proposed project would be subject to additional compliance and/or permitting requirements under state and federal regulations. Individual regulations, codes, and standards are described in Chapter 4, which evaluates the proposed project's impacts on specific environmental resources. The following federal, state, regional, or local permit approvals may be needed for the proposed project:

- Statewide General Waste Discharge Requirements for Dredged or Fill Discharges to Waters Deemed by the U.S. Army Corps of Engineers to be outside Federal Jurisdiction (General WDRs) for temporary impacts to the unnamed ephemeral drainage (Tesla Portal site only).
- Construction General Permit from Central Valley Regional Water Quality Control Board (RWQCB) for stormwater and groundwater discharges associated with construction activity where the activity disturbs more than one acre (Tesla Portal and Thomas Shaft Site).
- RWQCB Waste Discharge Requirement for discharge to land may be required if water is discharged to the artificial wetland or the containment basin on the Tesla Portal site and/or for discharges to the percolation tank at the Thomas Shaft site (Tesla Portal and Thomas Shaft sites).
- Section 1602 Permit from California Department of Fish and Game (CDFG) may be needed for temporary impacts from pipeline installation across an unnamed ephemeral drainage (Tesla Portal site only).
- Coverage under the San Joaquin County Multi-Species Habitat Conservation and Open Space Plan for potential impacts to species listed under the Federal and State Endangered Species Acts (Tesla Portal and Thomas Shaft sites).
- Modification to Regional Operational Permit will be issued by the California Department of Public Health for changes in disinfection equipment used (Tesla Portal and Thomas Shaft sites).

CHAPTER 4
Environmental Setting and Impacts

4.1 Approach to Analysis

Each environmental topic in this Environmental Impact Report (EIR) is analyzed with respect to significance criteria that are based on San Francisco Planning Department, Major Environmental Analysis (MEA) Division guidance. MEA guidance is, in turn, based on Appendix G of the California Environmental Quality Act (CEQA) Guidelines with some modifications. Categories used to determine impact significance are discussed below in Section 4.1.2. In determining the significance of a potential impact, the analysis first describes the nature, magnitude, and severity of a potential effect and determines whether or not it is applicable to the proposed *San Joaquin Regional Water Quality Improvement Project* (project), potentially significant, or less than significant. As part of the significance determination process, the analysis evaluates whether there are applicable regulations requiring compliance with measures that could reduce a potentially significant impact to a less-than-significant level. If so, compliance with the regulation is assumed, and the impact is considered to be less than significant.

The analysis also considers whether implementation of San Francisco Public Utilities Commission (SFPUC) Standard Construction Measures could avoid potential impacts. As described in Chapter 3, the SFPUC has established 10 construction measures that would be implemented as part of the proposed project. The objective of these measures is to minimize potential disruption of surrounding neighborhoods during construction and to reduce impacts on existing resources to the extent feasible. Each SFPUC project manager, environmental project manager, and construction manager would ensure that every project involving construction work contains uniform provisions to address these issues. The measures would apply to any construction activities that require environmental review and would be conducted by SFPUC staff or by outside contractors under contract with the SFPUC.

In cases where an impact would be potentially significant and there are no applicable regulations or SFPUC standard construction measure, or such regulations and measures exist but by themselves would not reduce an impact to a less-than-significant level, then the impact would remain potentially significant. If there are feasible measures available that could reduce these potentially significant impacts to a less-than-significant level, then the impact is considered potentially significant but mitigable, and the EIR identifies mitigation measure(s) to address the potentially significant impact. Impacts described in this chapter are numbered so they can be cross-referenced to the mitigation measures presented in Chapter 5.

Environmental impacts are assessed for the following areas:

4.2 Plans and Policies

4.3 Land Use and Visual Quality

4.4 Geology, Soils, and Seismicity

4.5 Hydrology and Water Quality

4.6 Biological Resources

4.7 Cultural Resources

4.8 Traffic, Transportation, and Circulation

4.9 Air Quality

4.10 Noise and Vibration

4.11 Public Services and Utilities

4.12 Agricultural Resources

4.13 Hazards

4.14 Energy Resources

4.15 Cumulative Effects

6.0 Growth-Inducement Potential and Indirect Effects of Growth

Except for the Cumulative Effects section and the Growth-Inducement Potential and Indirect Effects of Growth chapter, each section includes a brief introduction, description of the existing setting, and regulatory framework. Significance criteria are presented for each issue area, and project impacts are assessed in terms of those criteria. Sections conclude with a reference section. Mitigation measures are described in the sections, and presented in detail in Chapter 5.

The proposed project would have no effects in the following CEQA environmental topic areas: population and housing (however, the indirect effects of growth are discussed in Chapter 6, Growth-Inducement Potential and Indirect Effects of Growth); recreation; and wind and shadow. Potential impacts of the proposed project in these three environmental topic areas are discussed below.

- Inapplicable Population and Housing Impact Criteria

Induce substantial population growth in an area, either directly (for example, by proposing new homes and businesses) or indirectly (for example, through extensions of roads or other infrastructure. Implementation of the proposed project would not induce growth directly as the project does not propose to construct new homes or businesses in the area. Additionally, the project would not extend new roads or other infrastructure into undeveloped areas. Indirect growth inducement effects from implementation of the project as part of the overall Water System Improvement Program (WSIP) are addressed in Chapter 6, Growth-Inducement Potential and Indirect Effects of Growth.

Displace substantial numbers of existing housing units or create demand for additional housing, necessitating the construction of replacement housing. No housing would be displaced by the proposed project. Therefore, this impact would not apply at either site.

Displace substantial numbers of people, necessitating the construction of replacement housing elsewhere. No persons would be displaced by the proposed project. Therefore, this impact would not apply at either site.

- Inapplicable Recreation Impact Criteria

Increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated. The project does not include any proposal to construct new homes or businesses in the project areas that would result in localized population growth that would increase the use of existing neighborhood and regional parks or other recreational facilities. (Indirect growth inducement impacts from implementing the project as part of the overall WSIP are presented in Chapter 6, Growth-Inducement Potential and Indirect Effects of Growth.) Thus, no impact would occur.

Include recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment. The project does not include the construction or expansion of recreational facilities. Therefore, this impact would not apply.

Physically degrade existing recreational resources. The project includes improvements on lands that are owned and used by the SFPUC for its regional water system. No existing recreational resources would be physically affected. Therefore, this impact would not apply.

- Inapplicable Wind and Shadow Impact Criteria

Alter wind in a manner that substantially affects public areas. The Tesla Portal and Thomas Shaft sites are not located in proximity to any public areas, and the proposed project would have no effect on wind patterns that could affect such areas. Therefore, this impact would not apply.

Create new shadow in a manner that substantially affects outdoor recreation facilities or other public areas. The facilities that would be installed under the proposed project would create no

new shadows that would affect any recreational facilities or public areas. Therefore, this impact would not apply.

4.1.1 Impact Significance Categories

For the impact analyses, the following categories are used to describe impact significance:

Not Applicable (N/A). An impact is considered not applicable if there is no potential for impacts or if the environmental resource does not occur within the study area or the area of potential effects.

Less than Significant (LS). This determination applies if there is a potential for some limited impact, but not a substantial adverse effect that qualifies under the significance criteria as a significant impact. LS impacts do not require mitigation. These include impacts that would become less than significant with the implementation of SFPUC Standard Construction Measures, set out in Chapter 3, which are standard operating procedures of the agency and part of the project.

Potentially Significant, Mitigable (PSM). The PSM determination applies if there is the potential for a substantial adverse effect that meets the significance criteria, but mitigation is available to reduce the impact to a less-than-significant level.

Significant Unavoidable (SU). This determination applies if there is certainty for a substantial adverse effect that meets the significance criteria but for which there appears to be no feasible mitigation available to reduce the impact to a less-than-significant level. The word "potentially" is not used for impacts where it can be determined that: (1) the impact would occur; and (2) the impact could not be mitigated to a less-than-significant level. For SU impacts, mitigation would be required to the extent feasible even if the severity of the impact with mitigation would not be reduced to a less-than-significant level.

4.1.2 Water System Improvement Program

- As discussed in Section 1.2, the proposed project, along with several other facility improvement projects, are components of the SFPUC's WSIP. The Program EIR (PEIR), which was certified by the San Francisco Planning Commission on October 30, 2008, addressed the potential environmental impacts of the WSIP and evaluated regional water supply alternatives. Because the proposed project is a component of the WSIP the project would also contribute to the WSIP's water supply impacts.

- The PEIR analyzed potential water supply and system operations impacts (separate from environmental impacts associated with the facility improvements) within the following geographic regions: the Tuolumne River, Alameda Creek, Peninsula, and Westside Basin groundwater resources systems. The PEIR also identified the cumulative effects of implementing the WSIP and system operations in combination with other past, present, and reasonably foreseeable future projects within each of these watersheds. It also

discusses the potential effects of climate change and global warming on the regional water system.

- The WSIP would result in changes in reservoir levels and associated changes in downstream flows in rivers and creeks in the three affected watersheds, potentially resulting in groundwater, water quality, fisheries, and terrestrial biological resources,. In the event that deliveries to customers exceed 265 mgd (average annual), streamflow changes in the Tuolumne River watershed could affect fisheries and terrestrial biological resources. In the Alameda Creek and Peninsula watersheds, the WSIP, which includes restoring the historical storage capacities of Calaveras and Lower Crystal Springs Reservoirs, could affect reservoir levels, downstream flows, fisheries, and terrestrial biological resources. In addition, similar to the originally proposed WSIP, the WSIP will develop groundwater supplies in the North Westside Groundwater Basin as well as a conjunctive-use program in the South Westside Groundwater Basin.

- As stated above, the proposed project is a component of the WSIP and therefore would contribute also to the water supply impacts included in the tables below. Tables 4.1-1 through 4.1-4 summarize the WSIP water supply impacts and mitigation measures for each geographic region as analyzed in the PEIR. Table 4.1-5 lists cumulative water supply impacts. Appendix B.1 presents the program-level environmental impact analysis and mitigation measures for the water supply and system operations associated with the WSIP. In addition to water supply impacts and mitigation measures, the PEIR provides a program-level analysis of the impacts associated with facility improvement projects, including construction and cumulative construction, and operation impacts. This EIR addresses the same issues as the PEIR for the proposed project at a project-level detail.

Table 4.1-1
Summary of Water Supply Impacts and Mitigation Measures – Tuolumne River System and Downstream Water Bodies

Impact	Significance Determination					Mitigation Measures
		Biological Resource Impacts				
	All Impacts (except Biological Resources)	Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
STREAM FLOW						
Impact 5.3.1-1: Effects on flow along the Tuolumne River below O'Shaughnessy Dam.	LS					None required.
Impact 5.3.1-2: Effects on flow along Cherry Creek below Cherry Dam.	LS					None required.
Impact 5.3.1-3: Effects on flow along Eleanor Creek below Eleanor Dam.	LS					None required.
Impact 5.3.1-4: Effects on flow along the Tuolumne River below La Grange Dam.	LS					None required.
Impact 5.3.1-5: Effects on flow along the San Joaquin River and the Sacramento–San Joaquin Delta.	LS					None required.
GEOMORPHOLOGY						
Impact 5.3.2-1: Effects on sediment transport and channel characteristics between O'Shaughnessy Dam and Don Pedro Reservoir.	LS					None required.
Impact 5.3.2-2: Effects on sediment transport and channel characteristics below La Grange Dam.	LS					None required.
SURFACE WATER QUALITY						
Impact 5.3.3-1: Effects on water quality in Hetch Hetchy Reservoir and along the Tuolumne River below O'Shaughnessy Dam.	LS					None required.

Table 4.1-1
Summary of Water Supply Impacts and Mitigation Measures – Tuolumne River System and Downstream Water Bodies

Impact	Significance Determination					Mitigation Measures
		Biological Resource Impacts				
	All Impacts (except Biological Resources)	Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
Impact 5.3.3-2: Effects on water quality in Don Pedro Reservoir and along the Tuolumne River below La Grange Dam.	LS					None required.
SURFACE WATER QUALITY (cont.)						
Impact 5.3.3-3: Effects on water quality along the San Joaquin River and the Sacramento–San Joaquin Delta.	LS					None required.
SURFACE WATER SUPPLIES						
Impact 5.3.4-1: Effects on Tuolumne River, San Joaquin River, and Stanislaus River water users.	LS					None required.
Impact 5.3.4-2: Effects on Delta water users.	LS					None required.
GROUNDWATER						
Impact 5.3.5-1: Alteration of stream flows along the Tuolumne River, which could affect local groundwater recharge and groundwater levels.	LS					None required.
Impact 5.3.5-2: Alteration of stream flows along the Tuolumne River, which could affect local groundwater quality.	LS					None required.
FISHERIES						
Impact 5.3.6-1: Effects on fishery resources in Hetch Hetchy Reservoir.	LS					None required.

Table 4.1-1
Summary of Water Supply Impacts and Mitigation Measures – Tuolumne River System and Downstream Water Bodies

Impact	Significance Determination					Mitigation Measures
		Biological Resource Impacts				
	All Impacts (except Biological Resources)	Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
Impact 5.3.6-2: Effects on fishery resources along the Tuolumne River between Hetch Hetchy Reservoir and Don Pedro Reservoir.	LS					None required.
Impact 5.3.6-3: Effects on fishery resources in Don Pedro Reservoir.	LS					None required.
FISHERIES (cont.)						
Impact 5.3.6-4: Effects on fishery resources along the Tuolumne River below La Grange Dam.	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less; PSM if deliveries exceed 265 mgd					**Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water:** The SFPUC will pursue a water transfer arrangement with MID/TID and/or other water agencies which would offset the WSIP's effects on water storage in Don Pedro Reservoir and minimize WSIP-induced changes in releases from La Grange Dam. **If Measure 5.3.6-4a proves to be infeasible, the SFPUC will implement Measure 5.3.6-4b. **Measure 5.3.6-4b, Fishery Habitat Enhancement:** The SFPUC will implement or fund one of two fishery habitat enhancement projects that are consistent with the Lower Tuolumne River Restoration Plan; augmentation of spawning gravel at five selected sites or the filling or isolation from the river of one of the existing inactive quarry pits.
Impact 5.3.6-5: Effects on fishery resources along the San Joaquin River.	LS					None required.

Impact 5.7.5-1: North Westside Groundwater Basin.	LS							None required.
Impact 5.7.5-2: South Westside Groundwater Basin.	LS							None required.

NOTE: Significance determinations presented in this table assume implementation of all mitigation measures as they are presented in Chapter 5, Section 5.6, and described in Chapter 6.

4.2 Plans and Policies

4.2.1 Overview

This section first describes applicable land use plans and policies and then discusses the project's consistency with those applicable land use plans and policies. The focus is on land use plans and policies of agencies responsible for approving this EIR, namely the San Francisco Planning Commission, the San Francisco Public Utilities Commission (SFPUC), and the San Francisco Board of Supervisors. However, the relevance of the land use plans and policies of other agencies is also discussed.

Relevant resource-specific plans are described in Sections 4.3 through 4.15 (e.g., air quality management plans are discussed in Section 4.9, Air Quality, and the San Joaquin County Multi-Species Habitat Conservation and Open Space Plan is discussed in Section 4.6, Biological Resources).

4.2.2 Regulatory Framework

City and County of San Francisco Plans and Policies

The San Francisco City Charter, along with several other city plans and policies, guide the SFPUC's activities. City and County of San Francisco (CCSF) plans relevant to the proposed project are the San Francisco General Plan, the Accountable Planning Initiative, and the San Francisco Sustainability Plan. The San Francisco General Plan serves as a strategic and long term planning guide for San Francisco. The San Francisco Sustainability Plan addresses the long-term ability of the CCSF to meet the needs of its present citizens without compromising the ability of future generations to meet their needs. While in some cases CCSF land use plans and policies may apply to projects outside of San Francisco, they are primarily applicable to projects within San Francisco's jurisdictional boundaries.

Extraterritorial Lands

Under the San Francisco City Charter, Section 8B.121, the SFPUC has authority over the management, use, and control of extraterritorial lands, that is, properties outside of the San Francisco city limits that the CCSF owns or leases or over which it holds easements. Although the San Francisco General Plan and San Francisco Sustainability Plan were developed for lands within the jurisdictional boundaries of San Francisco, their underlying goals apply to SFPUC projects on extraterritorial lands. Section 8B.121 provides:

> Notwithstanding Charter Section 4.112, Under the San Francisco City Charter, Section 8B.121, the Public Utilities Commission shall have exclusive charge of the construction, management, supervision, maintenance, extension, expansion, operation, use and control of all water, clean water and energy supplies and utilities of the City as well as the real, personal and financial assets, that are under the Commission's jurisdiction or assigned to the Commission under Section 4.132.

California Government Code Section 53090 et seq. provides that the SFPUC receives intergovernmental immunity from the planning and building laws of other cities and counties. The SFPUC, however, seeks to work cooperatively with local jurisdictions where CCSF-owned facilities are sited outside of San Francisco to avoid conflicts with local land use plans and building and zoning codes. Also, the SFPUC is required under Government Code Section 65402(b) to inform local governments of its plans to construct projects or acquire or dispose of its extraterritorial property. The local governments have a 40-day review period to determine project consistency with their general plans. Under this requirement, the cities' or counties' determinations of consistency are advisory to the SFPUC rather than binding.

San Francisco General Plan

The San Francisco General Plan serves as a strategic and long term planning guide for San Francisco and is the comprehensive planning document governing land use decisions within the CCSF. It articulates the community's vision for the future through a description of goals, objectives, and policies that address the unique characteristics of San Francisco. One of the plan's basic goals is the "coordination of the growth and development of the city with the growth and development of adjoining cities and counties and of the San Francisco Bay Region." It contains the following plan elements: Air Quality; Arts; Commerce and Industry; Community Facilities; Community Safety; Environmental Protection; Housing; Recreation and Open Space; Transportation; and, Urban Design. In addition to the 10 plan elements, the San Francisco General Plan also includes 10 area plans that apply to different parts of the city.

The plan elements that are potentially relevant to the proposed project are briefly described below:

Air Quality Element. The objectives and policies of this element promote adherence to air quality regulations, focusing development near transit services, and advocating alternatives to the private automobile with the goal of clean air planning.

Commerce and Industry Element. This element functions as a guide for decisions related to economic growth and change. It addresses general citywide objectives as well as objectives for each of the major sectors of San Francisco's economy with its goals of continued economic vitality, social equity (with respect to employment opportunities), and environmental quality.

Community Safety Element. Protection of human life and property from hazards is the goal of this element. To that end, it discusses the potential for geologic, structural, and nonstructural hazards to affect city-owned structures and critical infrastructure.

Environmental Protection Element. This element encourages the protection of plant and animal life and fresh water sources. It also addresses San Francisco's responsibility of providing a permanent, clean water supply to meet present and future needs, as well as maintaining an adequate water distribution system.

Urban Design Element. The objectives and policies of this element support preserving landmarks and structures with notable historic, architectural, or aesthetic value.

Accountable Planning Initiative

In November 1986, the voters of San Francisco approved Proposition M, the Accountable Planning Initiative, which codified the following eight Priority Policies by adding Section 101.1 to the City Planning Code:

1. Existing neighborhood-serving retail uses shall be preserved and enhanced and future opportunities for resident employment in and ownership of such businesses enhanced.

2. Existing housing and neighborhood character shall be conserved and protected in order to preserve the cultural and economic diversity of our neighborhoods.

3. The City's supply of affordable housing shall be preserved and enhanced.

4. Commuter traffic shall not impede Muni transit services or overburden our streets or neighborhood parking.

5. A diverse economic base shall be maintained by protecting our industrial and service sectors from displacement due to commercial office development, and that future opportunities for resident employment and ownership in these sectors shall be enhanced.

6. The City shall achieve the greatest possible preparedness to protect against injury and the loss of life in an earthquake.

7. Landmarks and historic buildings shall be preserved.

8. Parks and open space and their access to sunlight and vistas shall be protected from development.

San Francisco Sustainability Plan

The San Francisco Sustainability Plan addresses the long-term ability of the CCSF to meet the needs of its present citizens without compromising the ability of future generations to meet their needs. The plan covers the following issue areas: air quality; biodiversity; energy, climate change and ozone depletion; food and agriculture; hazardous materials; human health; parks, open spaces and streetscapes; solid waste; transportation; water and wastewater; economy and economic development; environmental justice; municipal expenditures; public information and education; and risk management. For each topic, there is a set of indicators that are to be used over time to determine whether the CCSF is moving in a sustainable direction in that particular area. It should be noted that while the San Francisco Board of Supervisors endorsed the plan in 1997, it has not committed the City to perform the actions addressed in the plan.

- ***San Francisco Municipal Green Building Program***

- San Francisco's Green Building Program was founded in 1999 when the CCSF adopted the Resource Efficient Building Ordinance, which established green building standards for municipal buildings to increase energy efficiency, conserve CCSF finances, reduce the environmental impacts of demolition, construction, and operation of buildings, and create safe workplaces for CCSF employees and visitors. The ordinance created the inter-departmental Resource Efficient Building (REB) Task Force and charged the San Francisco Department of Environment with implementing the ordinance in partnership with the Department of Public Works and other REB Task Force departments. In 2004, amendments to Chapter 7 of the Environment Code set Leadership in Energy and Environmental Design (LEED) Silver Certification by the U.S. Building Council as the minimum environmental performance requirement for all municipal projects over 5,000 square feet. The REB Task Force assists City departments in compliance with the LEED Silver Certification requirement and helps to determine which projects are applicable for LEED ratings. For all municipal construction projects, including those projects that do not involve buildings and are not required to obtain LEED Silver Certification, the REB Task Force provides recommended best practices and sample specifications for building materials (e.g., recycled content of steel and concrete) (San Francisco Department of the Environment, 2004-2007).

SFPUC Policies

Water Enterprise Environmental Stewardship Policy

The SFPUC adopted the Water Enterprise Environmental Stewardship Policy in 2006. The policy establishes the long-term management direction for land owned by the CCSF, as well as for natural resources affected by operation of the SFPUC water system within the Tuolumne River, Alameda Creek, and Peninsula watersheds. Also addressed by the policy are rights-of-way and properties in urban settings under SFPUC management. The policy includes the following provisions:

- The SFPUC will proactively manage the watersheds under its responsibility in a manner that maintains the integrity of the natural resources, restores habitats for native species, and enhances ecosystem function.

- To the maximum extent practicable, the SFPUC will ensure that all operations of the SFPUC water system (including water diversion, storage, and transport), construction and maintenance of infrastructure, land management policies and practices, purchase and sale of watershed lands, and lease agreements for watershed lands protect and restore native species and the ecosystems that support them.

- Rights-of-way and properties in urban surroundings under SFPUC management will be managed in a manner that protects and restores habitat value where available, and encourages community participation in decisions that significantly interrupt or alter current land use in these parcels.

In addition, the Water Enterprise Environmental Stewardship Policy (SFPUC, 2006) calls for development of the Watershed and Environmental Improvement Program and the specific integration of the policy into the Water System Improvement Program (WSIP) and WSIP facility improvement projects, including the proposed project.

General Land Use Plans and Policies of Other Jurisdictions

The project sites are located in unincorporated San Joaquin County. Both sites are located on extraterritorial lands owned by the CCSF, and thus the SFPUC would not be legally-bound to the policies contained in the San Joaquin County General Plan. Nonetheless, the San Joaquin County General Plan is discussed to the extent that it provides land use planning information for the jurisdiction in which the project is located. This information is relevant to evaluate the impacts of the project with respect to the specific significance criteria under CEQA that require an analysis of the compatibility of a proposed project with certain aspects of local land use plans and policies. These particular significance criteria are listed below along with the location in this document where the reader can find the impact evaluation:

- Result in the loss of availability of a locally important mineral resource recovery site delineated on a local general plan, specific plan, or other land use plan (analyzed in Section 4.4, Geology, Soils, and Seismicity)

- Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance (analyzed in Section 4.6, Biological Resources)

- Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan (analyzed in Section 4.6, Biological Resources)

- Conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., conflict with policies promoting bus turnouts, bicycle racks, etc.), or would cause a substantial increase in transit demand that cannot be accommodated by existing or proposed transit capacity or alternative travel modes (analyzed in Section 4.8, Traffic, Transportation, and Circulation)

- Expose people to or generate noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies (analyzed in Section 4.10, Noise and Vibration)

- For a project located within an area covered by an airport land use plan (or, where such a plan has not been adopted, within 2 miles of a public airport or public use airport), expose people residing or working in the project area to excessive noise levels (analyzed in Section 4.10, Noise and Vibration)

- Conflict with existing zoning for agricultural use or a Williamson Act contract[1] (analyzed in Section 4.12, Agriculture Resources)

San Joaquin County General Plan 2010

The San Joaquin County General Plan 2010 (San Joaquin County, 1992) is the comprehensive, long-range public policy document designed to guide the use of private and public lands within the county. It describes the county's vision for its future and provides specific objectives, policies, and implementation actions for community development, public health and safety, and resources. The general plan is divided into three chapters (Community Development, Public Health and Safety, and Resources) that cover the seven mandatory elements required to be in general plans by state law (California Government Code Sections 65302-65303).

The overall intent of the San Joaquin County General Plan is to address the identified key issues confronting the county over the life of the plan, while being adaptable to changing conditions. Those issues are: accommodating rapid population growth; responding to pressures for increased housing while insuring a balancing increase in jobs; minimizing growth impacts on agricultural land; attracting high quality jobs; ensuring adequate water; improving air quality; protecting the Delta; improving the circulation system; paying for infrastructure and services; developing interjurisdictional coordination; and maintaining the quality of life. As stated in the San Joaquin

[1] Under a Williamson Act (Land Conservation Act of 1965) contract, the landowner agrees to limit the use of the land to agriculture and compatible uses for a period of at least 10 years. In return, the land is taxed at a rate based on the agricultural production of the land, rather than its real estate market value.

County General Plan 2010, its overall goal is to "Balance social, environmental, economic, cultural, and aesthetic concerns to provide a quality living environment."

The San Joaquin County General Plan land use designation for both project sites is General Agriculture (A/G). According to the General Plan, the A/G land use designation applies to areas suitable for agriculture outside areas planned for urban development where:

- The soils are capable of producing a wide variety of crops and/or supporting grazing
- Parcel sizes are generally large enough to support commercial agricultural activities
- There exists a commitment to commercial agriculture in the form of Williamson Act contracts and/or capital investments

Typical uses include crop production, feed and grain storage and sales, aerial crop spraying, and animal raising and sales. Additional activities such as mineral resource recovery, dairy canning operations, stockyards, animal feed lots, and sales yards require permits. According to the General Plan, agricultural activities must principally be used for crop production, ranching, and grazing. However, agricultural support activities and non-farm uses are permitted as long as they are compatible with the agricultural operations and satisfy the following criteria:

- The use requires a location in an agricultural area because of unusual site area requirements, operational characteristics, resource orientation, or because it is providing a service to the surrounding agricultural area
- The operational characteristics of the use will not have a detrimental impact on the management or use of surrounding agricultural properties
- The use will be sited to minimize any disruption to the surrounding agricultural operations
- The use will not significantly impact transportation facilities, increase air pollution, or increase full consumption

The San Joaquin County zoning designation for both project sites is AG-160 (General Agriculture). According to the San Joaquin County Development Title (Title 9), the purpose of the AG zone is to preserve agricultural lands for the continuation of commercial agriculture enterprises. The Development Title requires that lots zoned AG-160 be at least 160 acres. Additionally, both sites are also within an agricultural preserve (R-69-C1). The R-69-C1 is a resolution that was passed by the San Joaquin County Board of Supervisors, and it allows properties with an agricultural land use designation to enter into a Williamson Act contract (Griffin, 2007).

Habitat Conservation Plans

Habitat conservation plans provide comprehensive, long-term conservation measures for species listed as threatened or endangered under the California and Federal Endangered Species Acts, or for species that could be listed in the future. Section 4.6, Biological Resources, presents a discussion of the San Joaquin County Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) and addresses plan consistency.

4.2.3 Plan Consistency Evaluation

Approach to Analysis

The evaluation of plan consistency is based on the applicability of relevant land use plans and policies to the proposed project as they relate to:

- The underlying goals of the San Francisco General Plan and Sustainability Plan and the principal goals of the SFPUC Water Enterprise Environmental Stewardship Policy

As stated above, the San Francisco General Plan and Sustainability Plan are primarily applicable to projects located in San Francisco; however, they may also be applicable to projects on SFPUC extraterritorial land.

For these plans, a determination of potential consistency was made as required by Section 15125(d) of the CEQA Guidelines. However, because the policy language found in a land use plan is susceptible to varying interpretations, it is often difficult to determine whether a proposed project is consistent or inconsistent with such policies. Further, because land use plans often contain numerous policies emphasizing differing legislative goals, the project may be "consistent" with a general plan, taken as a whole, even though they may appear inconsistent with specific policies within the plan. The board or commission that enacted the plan or policy generally determines the meaning of such policies; these interpretations prevail if they are "reasonable," even though other reasonable interpretations are also possible. In light of these considerations, the consistency evaluation in this EIR represents the best attempt to advise the decision-makers as to whether the proposed project is consistent with applicable land use plans and policies.

Direct and indirect physical impacts resulting from project implementation are not addressed in this section, but in the appropriate technical sections of the EIR. For example, temporary impacts associated with dust and noise from project construction are addressed in Section 4.9 (Air Quality) and Section 4.10 (Noise and Vibration) of Chapter 4, respectively.

Consistency with San Francisco Plans and Policies

San Francisco General Plan

As described above in Section 4.2.2, the San Francisco General Plan addresses air quality, community protection from geologic and seismic hazards, protection of water resources,

biological resources, and other natural resources, construction-related noise, ambient air quality, and urban design as it relates to protection of historical and visual resources.

Although the project would result in impacts on air quality and natural resources, on the whole, it would mitigate such impacts. Implementation of the project would increase community safety, which would be a beneficial impact. Upgrading the existing disinfection facilities at the Tesla Portal site to meet current seismic, safety/fire, and building code standards would help protect the water system from the effects of earthquakes and other hazards. Moreover, new water treatment facilities at the Tesla Portal site that would meet federal and state requirements for water quality would help reduce the potential for a waterborne outbreak of gastrointestinal illness from *Cryptosporidium*. Additionally, the improvements at the Thomas Shaft site would help reduce the potential for a waterborne outbreak of gastrointestinal illness from *Giardia*. The project would, on the whole, be consistent with the San Francisco General Plan.

The San Francisco General Plan provides general policies and objectives to guide land use decisions. Any conflict between the proposed project and policies that relate to physical environmental issues are discussed in Sections 4.3 through 4.15. The compatibility of the proposed project with San Francisco General Plan policies that do not relate to physical environmental issues will be considered by decision-makers as part of their decision whether to approve or disapprove the proposed project. Any potential conflicts identified as part of the process would not alter the physical environmental effects of the proposed project.

Accountable Planning Initiative

Of the eight priority policies in the Accountable Planning Initiative, only policies six and seven are relevant to the proposed project. Policy six stipulates that the City achieve the greatest possible preparedness to protect against injury and the loss of life in an earthquake. Policy seven states that landmarks and historic buildings be preserved. The other priority policies are not applicable to the proposed project because the project site is not located in the CCSF and would have no effect on the viability of neighborhood-serving retail uses or housing and neighborhood character; increasing commuter traffic on local streets; or, blocking sunlight and views for CCSF parks and open space. Additionally, due to the nature of the proposed project (upgrading of existing water disinfection facilities), it would not affect preservation and enhancement of the city's supply of affordable housing, or displace industrial and service uses due to commercial office development.

With regard to policy six, earthquake preparedness, the proposed facilities are components of the SFPUC's WSIP. One of the primary goals of the WSIP is ensuring the reliability of the regional water system during a seismic event. The replacement of the Tesla Portal Hypochlorite Station with the new Chemical Process Building and Office/Control Building would result in a new chlorination facility that meets current seismic standards, taking the place of an existing chlorination facility that does not meet current seismic standards. This would reduce the vulnerability of the existing facility to earthquakes, as well as facilitating the continued operation of the chlorination facility should an earthquake occur.

With regard to policy seven's mandate to protect historic buildings, the proposed project would not alter or demolish historic resources. In addition, the historic resources identified at the Tesla Portal site would be maintained by SFPUC to prevent deterioration. Furthermore, the project's potentially significant impact of unintentional damage or destruction to historic resources due to the operation of construction equipment and storage of construction materials near the resource would be mitigated to a less-than-significant level by Mitigation Measures 4.7-3a (historical resources protection plan) and 4.7-3b (pre-construction surveys and vibration monitoring).

The proposed project would, on the whole, be consistent with San Francisco's Priority Policies, and would result in a beneficial impact related to earthquake preparedness.

San Francisco Sustainability Plan

The purpose of the San Francisco Sustainability Plan is to address the long-term environmental sustainability of San Francisco. The proposed project would be consistent with the goals of the sustainability plan because it proposes improvements that would increase the reliability of water supply to the city during earthquakes or other situations that could cause substantial damage and/or a system failure and would help reduce the potential for a waterborne outbreak of gastrointestinal illness from *Cryptosporidium* and *Giardia*.

- ***San Francisco Municipal Green Building Program***
- The San Francisco Municipal Green Building Program was developed for the purpose of improving the environmental performance of municipal buildings. The proposed project would be designed, constructed, and operated in accordance with the City's Green Building requirements. The SFPUC would complete and submit LEED checklists to the REB Task Force for the proposed project.

Water Enterprise Environmental Stewardship Policy

The proposed project would not be inconsistent with the underlying goals of the Water Enterprise Environmental Stewardship Policy. Of the potentially significant impacts on natural resources and habitat identified in Section 4.6, mitigation measures described in Chapter 5 identify approaches to reduce impacts to less than significant levels. Overall, the project as proposed would not result in habitat fragmentation or reduce ecosystem function.

Consistency with San Joaquin County Plans and Policies

San Joaquin County General Plan 2010

As described above, the SFPUC is not legally-bound by the land use policies of other local jurisdictions. The determination of project consistency with the local general plan would be made by the pertinent land use jurisdiction following preparation of this project-specific CEQA documentation and notification by the SFPUC pursuant to state law. Nonetheless, this EIR provides a brief analysis of the project's consistency with the San Joaquin County General Plan.

As noted above, on the whole, the intent of the San Joaquin County General Plan is to address the identified key issues confronting the county over the life of the plan, while being adaptable to changing conditions. The identified key issues confronting the county that are applicable to the project consist of: ensuring adequate water; improving air quality; and maintaining the quality of life. Project implementation of seismic, safety/fire, and building code upgrades at the Tesla Portal site would help protect the water system from the effects of earthquakes and other hazards, ensuring adequate water supplies. While project activities would result in impacts on air quality (mostly temporary construction impacts), the project would mitigate such impacts and would not

prevent the county from improving air quality. Finally, a clean, safe water supply is essential to good health and good quality of life. Implementation of the project would help protect the water supplied to LLNL Site 300 from potential contamination with *Cryptosporidium* and *Giardia*, helping to protect the health and maintain the quality of life of employees at the site. In general, the project would be consistent with the San Joaquin County General Plan.

Regarding the project's consistency with San Joaquin County resource protection goals, by preparing this EIR and conducting associated scoping and public outreach efforts, the CCSF has systematically identified the significant environmental impacts associated with project implementation as well as the feasible measures and alternatives to avoid or substantially lessen such effects. The significance criteria used in this EIR correlate with the intent of general plan goals and policies related to protecting the environment. As detailed throughout the remaining sections of Chapter 4, the majority of project impacts are related to construction, and these impacts would be reduced to less than significant levels, either through measures proposed as part of the project or otherwise committed to by the CCSF.

General Agriculture (A/G) Land Use Designation and Zoning

The San Joaquin County General Plan land use designation for both project sites is A/G. According to the General Plan, this designation applies to areas where soils are capable of producing a wide variety of crops and/or supporting grazing and there is a general commitment to agriculture with viable commercial agricultural enterprises. Additionally, according to the General Plan, non-farm uses are permitted in areas with the A/G land use designation if necessitated by their site area requirements or operational characteristics or if the use provides a service to the surrounding agricultural area (e.g., quarry operations). Further requirements that must be met are that the use must not negatively affect the management and operations of surrounding agricultural properties or significantly impact transportation facilities, increase air pollution, or increase full consumption. With the A/G land use designation, agricultural land uses are allowed, and public facilities are permitted; both of which are existing uses at the Tesla Portal site. Furthermore, implementation of the Tesla Treatment Facility would not result in a substantial intensification of use that would increase any potential inconsistencies with agricultural uses. Although there is no grazing lease at the Thomas Shaft site, the A/G land use designation would allow cattle grazing. Similarly, the AG-160 (General Agriculture) zoning of each site retains the option for agricultural land use, but also allows public facilities, such as those at the Tesla Portal and Thomas Shaft sites. Refer to Section 4.12 for a more detailed discussion of the project's potential to conflict with agricultural zoning.

4.3 Land Use and Visual Quality

4.3.1 Setting

Land Use

Tesla Portal Site

The Tesla Portal site, located approximately 7.5 miles south of the City of Tracy, is approximately 52 acres. The majority of the site is undeveloped, consisting of gently rolling hillsides covered by California annual grassland, with some cattle grazing onsite. A smaller, generally flat portion of the site is developed and contains the Tesla Portal Hypochlorite Station among other structures. As described in Chapter 3, the site contains several buildings and various water pipeline infrastructure. Three buildings, a wood-frame building housing the chlorination unit, a pump house, and a watershed keeper's cottage, were constructed in 1936, while two valve houses were added later, one in 1949 and the other in 1963. Located directly southwest of the Tesla Portal Hypochlorite Station is the Tesla overflow shaft, which is 5 feet in diameter and rises approximately 60 feet above ground elevation. Additionally, three 20,000-gallon water tanks are located on a hillside southwest of the shaft and buildings.

Large expanses of undeveloped grass-covered hillsides, scattered trees, occasional rural residential uses (homes, barns, outbuildings, tractors, etc.), utility lines, barbed wire fencing, and animal grazing form the defining features of the land surrounding the site. Agricultural land surrounding the site is used for animal grazing and is similar in nature to the undeveloped portions of the site (undeveloped, gently rolling hillsides covered by California annual grassland). The closest residential structure to Tesla Portal is located approximately 2,500 feet southeast of the project area, off West Vernalis Road. In addition, there are several ranch structures located approximately 750 feet west of the project area. The small, unincorporated community of Chrisman is located approximately 0.75 mile east of the Tesla Portal site. While still rural in character, Chrisman is more developed and built-up than the majority of the area surrounding the project site. A private golf course, the Tracy Golf and Country Club is located just east of Chrisman on the other side of South Chrisman Road. Refer to Figure 4.3-1a (Tesla Portal Existing and Surrounding Land Uses).

Thomas Shaft Site

The Thomas Shaft site, located approximately 4.4 miles southeast of the Tesla Portal site and approximately seven miles southwest of the City of Tracy, consists of approximately 28 acres that are mostly undeveloped and characterized by rolling hillsides covered with grassland and scattered oak trees. Approximately one acre of the site is developed with two facilities, a tunnel and access shaft (built when the Coast Range Tunnel was first installed in the area) and a backup chlorination facility that is used to chlorinate Hetch Hetchy water if adequate chlorination does not occur at the Tesla Portal Hypochlorite Station (refer to Figure 3-1 in Chapter 3, Project Description). Agricultural land uses, consisting of animal grazing, and open space surround the

site. There is a rural residence about 1.25 miles to the northeast of the facility. Lawrence Livermore National Laboratory (LLNL) Site 300 is located at the intersection of Thomas Shaft Road and Corral Hollow Road, about 1.5 miles to the north. LLNL Site 300 contains a variety of office buildings and other structures. Refer to Figure 4.3-1b (Thomas Shaft, Existing and Surrounding Land Uses).

Visual Quality

Tesla Portal Site

The Tesla Portal site is located approximately 0.75 miles southwest of Interstate 580 (I-580) and about 0.75 miles west of the rural unincorporated residential development of Chrisman. Natural, rural qualities characterize the largely undeveloped site, with rolling hills in the south and generally flat grassland in the north. A small cluster of buildings occupies the flat portion of the property. Three water tanks are located on the hillside south of the buildings. The area immediately north, west, and south of the site are generally undeveloped and visually defined by open space used for ranching operations and the rural residential development of Chrisman to the east. Photographs of the existing visual conditions of the Tesla Portal site are provided in Figures 4.3-3a, b, c, d, and e (Tesla Portal Visual Conditions). Figure 4.3-2 (Tesla Portal Viewpoint Locations) shows the locations where the photographs were taken.

Only a small portion of the Tesla Portal site is developed. Existing structures on the site include a manifold structure, the Tesla overflow shaft, caretaker's cottage, caretaker's garage, chlorinator building, pump house/equipment, northwest valve house, southwest valve house, and an office/storage building. The Tesla overflow shaft is 5 feet in diameter and rises approximately 60 feet above ground elevation. The caretaker’s cottage and some of the various other structures are generally similar in terms of design and reflect the California Craftsman style with concrete foundations, featuring concrete stucco-clad walls and double-gabled composition shingle clad roofs. The architectural details include double-gabled roof features, overhanging eaves and decorative knee-brace roof brackets on the gable ends. The gable end peaks feature basket-weave lattice wood vents above the plaster walls. The valve houses reflect the Spanish Revival style, with concrete foundations, concrete stucco-clad walls and clay tile gable roofs. The potential historic qualities of these structures are described in Section 4.7, Cultural Resources.

There is permanent exterior lighting on five existing street lamps on the Tesla Portal site: two near the main gate, one on the power pole at the entrance to the Coast Range Tunnel, one half way up the road towards the main entrance of the facility, one near the back gate, and one on a power pole adjacent to the building that contains the Tesla Portal Hypochlorite Station. In addition, each building has exterior lighting, including motion-sensor lighting, on the buildings over the doors and on the side walls.

Figure 4.3-3e

Contributing to the rural qualities of the site is the existing vegetation, which consists of California annual grassland and non-native trees. There is an artificial wetland area that lies approximately 100 feet west of the existing access road leading up to Tesla Portal. The wetland is approximately 0.308 acres in size and extends 850 feet northwest of the current facilities. There is a row of trees directly north of the existing buildings and California annual grassland north of the trees. The hills south of the existing facilities are covered with California annual grassland as well.

There are two State Designated Scenic Highways located in San Joaquin County. I-580 is an officially designated State Scenic Highway from Interstate 5 (I-5) to the Alameda County line. I-5 is an officially designated State Scenic Highway from the Stanislaus County line to I-580 (California Department of Transportation, 2008). As shown in Figure 4.3-2e, there are distant views of the Tesla Portal site from I-580; however, much of the facility is shielded from view by trees. San Joaquin County General Plan has designated 12 scenic routes throughout the county. Within the vicinity of the Tesla Portal site, the San Joaquin County General Plan identifies I-580 and I-5 from Stanislaus County to the Alameda County line for a length of 16 miles as scenic routes (essentially equivalent to the Caltrans officially designated routes).

Thomas Shaft Site

The Thomas Shaft site and the area immediately surrounding it are characterized by undeveloped, gently rolling hills covered with California annual grassland and occasional oak trees. Approximately one acre of the site is developed and contains the Thomas Shaft Chlorination Facility and associated structures. Areas surrounding the project site are used for cattle grazing. Access to the site is via Thomas Shaft Road, a private road starting at Corral Hollow Road about 1.5 miles north of the site. Contributing to the rural character of the area are a farmhouse, shed, and associated facilities located approximately 1.25 miles northeast of the project site. Photographs of the existing visual conditions of the site are provided in Figure 4.3-4 (Thomas Shaft Visual Conditions).

The Thomas Shaft Chlorination Facility is a concrete structure surrounded by a chain link fence. While no lighting is provided along the existing roadway, there are outdoor light fixtures attached to the building. These lights are used for gate access and to light the doorways leading into the facility.

There are no State Scenic Highways located in the immediate vicinity of the Thomas Shaft site, and the nearest Scenic Highway is a 16-mile portion of I-580 and I-5 between Stanislaus and Alameda counties. San Joaquin County General Plan has designated 12 scenic routes throughout the county. Within the vicinity of the Thomas Shaft site, Corral Hollow Road is a designated scenic route. However, because of the topography of the surrounding area and distance from Corral Hollow Road to the site, the Thomas Shaft facilities are not visible from this scenic road.

4.3.2 Regulatory Framework

Refer to Section 4.2 (Plans and Policies) for a discussion of the regulatory and planning framework for the proposed project, and analysis of the project's consistency with relevant plans and policies. Information is provided below for other adopted regulations and policies that govern visual quality in the project vicinity.

Visual Quality

California Scenic Highway Program

In 1963, California's Scenic Highway Program was established to protect and enhance the natural scenic beauty of California highways and adjacent corridors, through special conservation treatment. The scenic highway program consists of eligible and officially designated routes. A highway may be designated as *eligible* for listing as a state scenic highway if it offers travelers scenic views of the natural landscape, largely undisrupted by development. Eligible routes advance to *officially designated* status when the local jurisdiction adopts ordinances to establish a scenic corridor protection program and receives approval from the California Department of Transportation (Caltrans).

Scenic Highways Element of the San Joaquin County General Plan

The Scenic Highways Element of the San Joaquin County General Plan was adopted by the Board of Supervisors on October 19, 1978. The purpose of the element is to establish scenic routes in the county and to guide the preservation and enhancement of scenic qualities and natural scenic areas adjacent to and visible from scenic routes.

4.3.3 Impacts

Significance Criteria

The City and County of San Francisco has not formally adopted significance standards for impacts related to land use and visual quality, but generally considers that implementation of a proposed project would have significant impacts to these resources if it were to:

Land Use

- Physically divide an existing community
- Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect (analyzed in Section 4.2, Plans and Policies)
- Have any substantial impact upon the existing character of the vicinity

- Substantially disrupt or displace existing land uses or land use activities

Visual Quality

- Have a substantial adverse effect on a scenic vista including views from a designated scenic highway or road
- Substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and other features of the built or natural environment which contribute to a scenic public setting
- Substantially degrade the existing visual character or quality of the site and its surroundings
- Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area or which would substantially impact other people or properties

Areas of No Project Impact

Land Use

As described above, the areas surrounding both sites contain little or no development, and the construction of the proposed improvements and their on-going operation would not physically divide an existing community. These SFPUC facilities are currently used for water system purposes and the facilities would continue to perform their current function once construction is complete. The proposed project would have no impact with respect to this significance criterion.

Visual Quality

The Thomas Shaft site, and therefore, also the project activities proposed at this location, is not visible from any scenic vistas or scenic roadways including Corral Hollow Road. The UV system would be installed within the existing Chlorination Facility building. The new prefabricated building placed over the Thomas Shaft would be constructed out of an eight foot steel frame surrounded by metal siding. The new building would be designed to be visually compatible with the existing facility and would not change the character of the site. Therefore, the project improvements at the Thomas Shaft site would not have construction or operational impacts with respect to this significance criterion.

The Thomas Shaft site is located about 1.5 miles south of Corral Hollow Road and approximately 1.25 miles southwest of the nearest rural residence. Given the distance of the site from Corral Hollow Road and from any residential uses, the project would not degrade the existing visual character or quality of the site or its surroundings and no impact would result. The Thomas Shaft site has existing lighting: however, no additional exterior lighting would be installed at the site. Therefore, the proposed project at Thomas Shaft would not create a new source of light or glare and would have no impact to day or nighttime views. These areas of no impact are not discussed further for the project components at the Thomas Shaft site.

Approach to Analysis

The land use analysis evaluates short-term impacts on existing land uses resulting from temporary construction activity. Construction and operation of the proposed project at Tesla Portal and Thomas Shaft sites would occur within the existing site boundaries. Potential physical environmental effects on surrounding land uses resulting from implementation of this project are addressed in the respective sections of this EIR, including Section 4.7, Cultural Resources; Section 4.8, Traffic, Transportation, and Circulation; Section 4.9, Air Quality; and Section 4.10, Noise and Vibration.

The analysis of visual resources identifies potential temporary and permanent adverse visual impacts that the project can have on scenic vistas, as seen from scenic highways, or on other visual resources. For analysis of impacts on scenic vistas, information was compiled from Caltrans' list of designated scenic highways (California Department of Transportation, 2008).

Land Use

Project consistency with applicable plans and policies is analyzed in Section 4.2, Plans and Policies. The remaining significance criteria are addressed below.

Construction Impacts

Impact 4.3-1: Temporary disruption or displacement of existing land uses during construction (Tesla Portal: LS; Thomas Shaft: LS)

For the purposes of this analysis, a combination of noise, vibration, dust, traffic congestion, and/or access disruption constitutes a temporary land use disruption. As stated above, these potential impacts are evaluated individually in the respective sections of this EIR.

The proposed improvements and construction staging would occur at existing SFPUC facility sites that are currently used for water system purposes, and the facilities would continue to perform their current functions during construction; therefore, construction operations would not significantly or adversely disrupt or displace existing onsite land uses. Furthermore, due to the remoteness of both the Tesla Portal and Thomas Shaft sites, project construction activities would remain isolated from other developed land uses.

Tesla Portal Site

The proposed improvements at the Tesla Portal site would occur within existing site boundaries. It is possible that a combination of construction noise, vibration, dust, traffic congestion and/or access disruption could temporarily affect residential uses near the Tesla Portal site; however, the construction phase would be short-term and temporary, and the surrounding area is open space/grassland, with the nearest residential area 0.5 mile away.

The construction of the improvements at the Tesla Portal site would use an approximately nine-acre, undeveloped grassland area located on the site on both sides of the entrance road for staging. No other equipment and materials staging areas and/or temporary construction easements are anticipated for the construction of the improvements at the Tesla Portal site. Therefore, impacts associated with temporary disruption or displacement of existing land uses during construction would be less than significant.

Thomas Shaft Site

At the Thomas Shaft site, proposed improvements would occur within existing SFPUC site boundaries. Additionally, there is sufficient space at the Thomas Shaft site for equipment and materials staging areas; therefore, there would not be any use of properties adjacent to the site for staging and/or need for temporary construction easements. Therefore, impacts associated with temporary disruption or displacement of existing land uses during construction would be less than significant.

Impact 4.3-2: Temporary impact to the existing character of the vicinity (Tesla Portal: LS; Thomas Shaft: LS)

The area surrounding both project sites is rural in character. Construction activities associated with new development under the proposed project would be confined to a relatively small area on both sites, which would leave the majority of the sites undeveloped and would not have a substantial adverse impact on the existing character of the vicinity. Therefore, a less than significant impact would result.

Operational Impacts

Impact 4.3-3: Substantially impact the existing character of the vicinity (Tesla Portal: LS; Thomas Shaft: LS)

The area surrounding the project sites would remain rural in character after construction is complete. As the project does not propose any changes in the general use of either the Tesla Portal or Thomas Shaft sites and the proposed improvements would be confined to a relatively small portion of each site, with the remainder left as undeveloped open space, project operation would not have a substantial adverse impact upon the existing character of the vicinity. Therefore, a less than significant impact would result.

Visual Quality

Construction Impacts

Impact 4.3-4: Temporary construction-related adverse impacts on scenic vista or scenic resources (Tesla Portal: LS; Thomas Shaft: N/A)

Construction activities typically have only temporary effects on a scenic vista or scenic resource and, therefore, are generally considered to have a less-than-significant impact. However, construction projects that would be located at a site for a year or more could result in construction-related visual impacts.

Work proposed at the Tesla Portal site is scheduled to last for approximately 24 months, and construction activities would consist of excavation, relocation of existing utilities, site grading, structural work, mechanical/process system work, and electrical work. Nighttime lighting of the construction staging and development areas is proposed to provide security during construction, and could also occur during tie-in of the new facilities. Construction staging areas, graded surface, construction materials, equipment and truck traffic would be located approximately 0.75 mile from I-580, a State Designated Scenic Highway and a scenic route designated by San Joaquin County General Plan. Project construction would have a minimal effect on the scenic characteristics of the undeveloped portion of the site where construction staging and development would occur.

As described in Chapter 3, the SFPUC would implement Standard Construction Measure #10 as part of the project, to reduce visibility of staging areas, maintain a clean and orderly site, and nighttime lighting would be directed away from residential areas during construction. Therefore, construction-related visual impacts would be considered less than significant.

Operational Impacts

Impact 4.3-5: Permanent adverse impacts on scenic vistas or scenic resources (Tesla Portal: PSM; Thomas Shaft: N/A)

At the Tesla Portal site, new facilities, including three new buildings, new paved areas and security improvements, (refer to Chapter 3, Project Description), would be constructed northeast of existing structures, on approximately three acres that currently is undeveloped grassland.

There are distant views of the Tesla Portal site from I-580, which is a State Designated Scenic Highway (from I-5 to the Alameda County line), and a scenic route designated by San Joaquin County General Plan, and located approximately 0.75 miles north of the site. Existing views from I-580 of the larger project vicinity generally illustrate a rural setting with undeveloped rolling hills serving as a backdrop to farmland and grazing land with intermittent development comprised of farm structures or other clustered development (e.g., the community of Chrisman, and the

Tesla Portal site). The existing structures at Tesla Portal are somewhat visible from I-580, although much of the facility is shielded from view by trees and located at such a distance that the facilities are not fully visible (refer to Figure 4.3-2c). The proposed buildings would be 12 feet tall (Office and Control Building) and 32 feet tall (Chemical Process Building and UV Disinfection Facility), and likely constructed out of concrete and steel with some glass details. The proposed structures would be located northeast of existing facilities and northeast of the existing screen of trees.

The construction of new buildings could result in potentially significant visual impacts to a scenic resource as viewed from I-580 because the project would increase the onsite concentration of structures, thereby incrementally contributing to an interruption of views of the surrounding rural character and rolling hills. New buildings would be visible from I-580 and the structures would not be shielded from view by trees or any other vegetation. However, this impact would be mitigated through project design, which would require the new structures to be visually compatible with existing adjacent structures. Implementation of Mitigation Measures 4.3-5a and 4.3-5b, require architectural design to be compatible with existing development and landscaping screens (berms or plantings), to ensure that project development would maintain the visual and aesthetic setting of the project site relative to the existing built conditions.

The project proposes improvements to the existing Tesla Portal manifold; however, these improvements would not contribute to the onsite building density, nor would such improvements be visible from offsite locations.

The project would also construct a microwave tower that would extend up to 100 feet in height with two 8-foot-diameter microwave dishes mounted at the top of the tower at the Tesla Portal site. The new microwave tower would be located just north of the three existing water tanks, and would be visible from offsite locations, including I-580. The proposed microwave tower would be visible from a distance but would have three existing 20,000-gallon water tanks, with an elevation of approximately 13 and a half feet as a backdrop, so the tower would not be as noticeable.

Proposed site improvements and site-disturbing activities at the Tesla Portal site would be within areas that contain no trees, rock outcroppings, or other scenic resources. Therefore, with implementation of project mitigation measures, impacts on scenic vistas or scenic resources would be less than significant.

Impact 4.3-6: Substantially degrade the existing visual character or quality of the sites (Tesla Portal: LS; Thomas Shaft: N/A)

The Tesla Portal site is located in a rural environment characterized by water utility operations, ranching operations, grazing and a nearby rural residential area. The majority of the 52-acre site is undeveloped and only 3.2 acres of the site would be developed as a result of the project. The

proposed structures that would be visible from West Vernalis Road include a 14,000-square-foot Chemical Process Building (32 feet in height), a 3,500-square-foot Office/Control Building (12 feet in height), and a 20,000-square-foot UV Building (32 feet in height). Two diesel standby generators are proposed adjacent to the UV Building, two 15,000-gallon above ground diesel fuel tanks are proposed adjacent to the Chemical Process Building, and the existing manifold would be encased with a steel or concrete structure and covered with soil. In addition, a microwave tower would be installed adjacent to the three existing water tanks located on the hillside above the other existing structures on the site.

Although the project would add structures to the site, new facilities would be confined to a relatively small portion of the site, and the remainder of the site would remain as undeveloped open space. Additionally, the project would be designed to be visually compatible with existing facilities. Therefore, although the project would incrementally contribute to on-site development, the project would not substantially degrade the visual character and quality of the site and a less than significant impact would result.

Impact 4.3-7: The proposed project would introduce new sources of light and glare into the project area (Tesla Portal: LS; Thomas Shaft: N/A)

The existing facilities at Tesla Portal contain five street lamps and exterior lighting on buildings including some motion-sensor light fixtures. The proposed lighting system at Tesla Portal would be designed utilizing a minimum number of fixtures with illumination levels based on the recommendations of the Illumination Engineering Society of North America and the guidelines of California Code of Regulations Title 24. Pole mounted high-pressure sodium or metal halide lamps would be used for outdoor areas such as roadways and parking areas. Along new building exterior walls, compact fluorescent or low-wattage metal halide lamp fixtures would be used.

The project proposes new, permanent sources of lighting that could affect nighttime views from the I-580 (0.65 miles north) and the nearby residential area of Chrisman (0.75 miles east). However, given the distance to the nearby highway and residential uses and the proposed design of new exterior lighting, impacts would be less than significant. Additionally, the new structures at the Tesla Portal site would be consistent with the character of the existing structures and would utilize non-reflective building materials; therefore, the exterior surfaces of the proposed buildings would not be a significant source of glare during daytime hours.

4.4 Geology, Soils and Seismicity

4.4.1 Setting

Regional and Local Geology

Tesla Portal Site

The Tesla Portal site is located along the western edge of the San Joaquin Valley at the boundary between the Great Valley Geomorphic Province and Coast Ranges Geomorphic Province.[1] Located in central California, the Great Valley Geomorphic Province is approximately 430 miles long and 50 miles wide bounded to the north by the Klamath Mountains and Cascade Range, to the south by the Tehachapi Mountains, to the east by the Sierra Nevada Mountains and to the west by the Coast Ranges. The Great Valley is underlain by alluvial sedimentary deposits of Quaternary and Tertiary age occupying a structural trough more than 30,000 feet thick. This sedimentary sequence is in turn underlain by a basement complex of Mesozoic intrusive igneous rocks and sedimentary and volcanic rocks at various stages of metamorphism and deformation (Norris and Webb, 1976). The Coast Ranges Geomorphic Province extends approximately 600 miles north and south along the California coastline and is comprised mainly of the Franciscan Assemblage of Mesozoic age and marine and continental sedimentary rocks of Cretaceous to Quarternary age.

The San Joaquin Valley is a level, sediment-filled depression, more than 250 miles long and 40 miles wide, that evolved during the Cenozoic age as a result of plate tectonics and sea level changes (Bartow, 1991). The San Joaquin Valley is comprised of marine sedimentary rock that ranges in age from Jurassic to Cretaceous, overlain by Cenozoic to Quaternary continental deposits. The marine sedimentary rock in the region comprises undifferentiated Upper Cretaceous sedimentary rock, and sandstone and shale of the Panoche and Marino Formations. The continental deposits that overlay the marine deposits are comprised of moderately consolidated sedimentary rock and volcanic deposits that outcrop in the foothills along the flanks of the valley. Poorly consolidated alluvial deposits containing gravel, sand, silt, and clay are present on the valley floor. Tesla Portal lies along the western edge of the San Joaquin Valley, where surface soils are comprised mainly of finer-grained alluvium: loams, clay loams and clays derived from the Coast Ranges to the west.

The Tesla Portal site is located on the eastern side of the Coast Ranges within the Tracy Quadrangle (USGS, 1981). The topography at Tesla Portal is relatively flat on the eastern portion of the site where the structures that would comprise the Tesla Treatment Facility are proposed, but becomes steeper west of the existing structures on the site rising from an elevation of approximately 385 feet to 405 feet above mean sea level (feet msl) (MACTEC, 2007). The existing developed portion of the site is located between the 375 and 395 feet msl.

[1] A geomorphic province is an area that possesses similar bedrock, structure, and history.

Thomas Shaft Site

The Thomas Shaft site, approximately 4.4 miles southwest of Tesla Portal, is located in the Diablo Range, on the eastern edge of the Coast Ranges Geomorphic Province where it borders the Great Valley Geomorphic Province. The Diablo Range is underlain by Franciscan Assemblage rocks that originated from oceanic crust accreted to the continental margin, while the Great Valley Geomorphic Province is characterized by a thick sequence of marine and nonmarine sediments. The earliest sedimentary rocks of the Great Valley sequence are approximately the same age as the Franciscan rocks. The Great Valley sequence rocks have been uplifted on the west by upfaulting of the Coast Ranges, so the oldest exposed sedimentary rocks in the sequence tend to be on the west, in contact with the Franciscan rocks, and are younger toward the San Joaquin Valley.

The Thomas Shaft site is underlain by marine sandstone, mudstone, shale, and minor volcanic tuff belonging to the Upper Miocene San Pablo Group, which is locally mainly represented by sandstones of the Cierbo and Neroly Formations. The San Pablo Group was deposited over Middle Miocene marine shales and sandstones belonging to the Monterey Group (called the Monterey Formation west of the San Andreas Fault). The Monterey Group rocks are not exposed in the vicinity of the Thomas Shaft site; instead the San Pablo Group rocks are in fault contact with Franciscan rocks west of the Carnegie Fault.

The Thomas Shaft site is located within the Lone Tree Creek Quadrangle (USGS, 1994), east of the Livermore Valley and on the east-facing side of the Coast Ranges. The site topography is relatively flat and is located at an elevation of approximately 700 feet msl, and surrounded by gently rolling hills, steeper in some locations.

Soils

Soils are formed by the forces of weather and organisms on parent materials, such as rocks or sediments. The physical action of rivers and streams carry and disperse the fragmented material. The resulting soils of an area vary depending on the climate, the number and kind of living organisms, source materials, relief and drainage, and physiochemical changes sometimes due to the acts of man. The combination of these processes determines the physiography and soils of an area.

Problematic soils, including corrosive and expansive soils, can cause damage to structures and buried utilities and can also increase required maintenance. Depending on the degree of corrosivity of subsurface soils, concrete and reinforcing steel in concrete structures and bare-metal structures exposed to these soils can deteriorate, eventually leading to structural failures. Expansion and contraction of expansive soils in response to changes in moisture content can cause differential and cyclical movements that can cause damage and/or distress to structures and equipment.

Corrosivity of soils is commonly related to several key parameters: soil resistivity, presence of chlorides and sulfates, oxygen content, and pH. Typically, the most corrosive soils are those with

the lowest pH and highest concentration of chlorides and sulfates. Cyclic wet/dry conditions can result in a concentration of chlorides and sulfates as well as mechanical action that tends to break down protective corrosion films and coatings on the surface of building materials. High-sulfate soils are also corrosive to concrete and may prevent complete curing, reducing its strength considerably. Low pH and/or low-resistivity soils can corrode buried or partially buried metal structures.

Expansive soils are characterized by their ability to undergo significant volume change (shrink and swell) due to variations in soil moisture content. Changes in soil moisture can result from rainfall, landscape irrigation, utility leakage, roof drainage, and/or perched groundwater.[2] Expansive soils are typically very fine grained with a high to very high percentage of clay.

The soils of San Joaquin County have been characterized primarily for agricultural purposes by the U.S. Department of Agriculture, Soil Conservation Service (SCS) (SCS, 2002). Field work was completed in April 1988 and the areal distribution of soil units was plotted on aerial photographs from the period from 1970 to 1977 at a scale of 1:24,000 (1 inch to 2,000 feet). The following paragraphs discuss SCS interpretations of soils at each of the project sites.

Tesla Portal Site

The area directly east of the Tesla Portal site is underlain by Holocene alluvial fan deposits shed by arroyos draining the Coast Ranges. The material directly north of the existing structures on the Tesla Portal site is fill as much as 25 feet thick, which in turn overlies native alluvium consisting of gravelly sand and silty sand. The fill is believed to be the edge of a large area of excavation material (tunnel muck) placed there during construction of the Coast Range Tunnel. The material appears to be uncompacted and consists of clays and silts of varying consistencies. This material varies from 10 to 25 feet thick at the locations tested (MACTEC, 2007).

Native soils surrounding and underlying the fill at the Tesla Portal site are relatively strong, consisting of stiff to hard silts and clays, and dense sands, and extend to depths in excess of 20 feet below ground surface (bgs). According to the SCS report (2002), soils uphill of the Tesla Portal are classified as the Calla-Carbona complex, with 8 to 30 percent slopes, whereas soils between the portal and the San Joaquin Valley are designated Carbona clay loam, with 2 to 8 percent slopes. Both soil types exhibit slow permeability and high shrink-swell potential. In addition, the Calla-Carbona soils yield rapid runoff and demonstrate a moderate to severe water erosion hazard.

The area south of Tesla Portal is underlain by consolidated sediments that are mapped as late Tertiary (late Pliocene to Miocene) Fanglomerate. This reddish-brown to gray conglomerate, sandstone, and siltstone is composed primarily of detritus from the Franciscan Complex or the Great Valley sequence sedimentary rocks.

[2] Perched groundwater is a local saturated zone above the water table. It typically exists above an impervious layer (such as clay) with limited extent.

Thomas Shaft Site

According to SCS (2002), the vicinity of the Thomas Shaft is underlain by soils of the Alo-Vaquero complex, with 30 to 50 percent slopes. These steep soils are located in mountainous areas. The Alo clays (45 percent of the unit) form on parent material consisting of shales, whereas the Vaquero clays (40 percent of the unit) form on sandstone parent materials. Both soil types exhibit slow permeability, high shrink-swell potential, and severe hazard of water erosion due to rapid rainfall runoff. The remainder of the area is underlain by small zones of Wisflat, Arburua and San Timoteo soils in convex positions near the tops of slopes.

Seismicity

The Alquist-Priolo Earthquake Fault Zoning Act (Alquist-Priolo Act) of March 1973 required the State of California to delineate earthquake fault zones along known active faults in California. The Alquist-Priolo Act further required cities and counties to regulate certain development projects within the zones. A summary of principal provisions of the Alquist-Priolo Act and implications is presented in the California Geologic Survey (CGS) publication of Hart and Bryant (1997), "Fault-Rupture Hazard Zones in California." A major objective of the CGS's continuing fault evaluation and zoning program is to evaluate and update potentially active faults in California for zoning consideration.

A *fault* is defined as a fracture or zone of closely associated fractures along which rocks on one side have been displaced with respect to those on the other side. Most faults are the result of repeated displacement that may have taken place suddenly or by slow creep. A fault is distinguished from those fractures or shears caused by landsliding or other gravity-induced surficial failures (Hart and Bryant, 1997).

A *fault zone* is a zone of related faults that commonly are braided and subparallel, but may be branching and divergent. A fault zone has significant width (with respect to the scale at which the fault is being considered, portrayed, or investigated), ranging from a few feet to several miles (Hart and Bryant, 1997).

Pursuant to the Alquist-Priolo Act, an "*active*" fault is defined by the State of California as a fault that has had surface displacement within Holocene time (e.g., the last 11,000 years). Surface displacements are observable and can be measured either from rock outcrops or within a trench dug across a fault trace. A "*potentially active*" fault is defined as a fault that has shown evidence of surface displacement during the Quaternary (last 1.6 million years), unless direct geologic evidence demonstrates inactivity for all of the Holocene or longer. This definition does not mean that faults lacking evidence of surface displacement are necessarily inactive.

"Sufficiently active" is used to describe a fault where there is some evidence that Holocene displacement occurred on one or more of its segments or branches (Hart and Bryant, 1997).

Subsequent to the passage and implementation of the Alquist-Priolo Act, the SFPUC developed General Seismic Requirements for Design of New Facilities and Evolution and Upgrade of

Existing Facilities (2006). That document adopted three classes of faults to be considered in all SFPUC projects, as follows:

1. Active Faults – Those faults that have had movement within the past 11,000 years.

2. Potentially Active Faults – Those faults that could potentially generate an earthquake, and which have not been proven to have had no movement within the past 11,000 years.

3. Secondary Faults – Possible future displacements in response to a major earthquake on a nearby active fault (sometimes called sympathetic fault displacement). No secondary faults are mapped in the vicinity of the project; accordingly, this terminology is not used in this report.

This nomenclature (active and potentially active) is used in discussions of seismicity in this analysis. The San Joaquin Valley is a relatively seismically quiescent area located between two areas of documented fault activity. The Coast Ranges to the west contain historically active faults that are associated with the San Andreas Fault System, including the Hayward, Greenville, and Calaveras faults (Jennings, 1994a, b). Seismic shaking and potential ground deformations at the project sites (Tesla Portal and Thomas Shaft) are governed by two seismic source areas, as discussed in the following paragraphs.

San Andreas Fault Zone

A region of high seismic activity, the Coast Ranges of western California contain both active and potentially active faults. The USGS 2002 Working Group on California Earthquake Probabilities has evaluated the probability of one or more earthquakes of moment magnitude 6.7 or higher occurring in the San Francisco Bay Area. The study concluded that there is a 62 percent probability that such a major earthquake will strike the San Francisco Bay Area before 2032 (USGS, 2003).

The San Andreas Fault Zone extends nearly the entire length of California and marks the plate boundary between the North American plate to the east and the Pacific plate to the west. The San Andreas is not represented by a single trace, but by a system of faults that diverge from the main fault south of San Jose. Three of the active faults included in the San Andreas Fault System, the Caleveras, Greenville, and Hayward Faults, are within 50 miles of the Tesla Portal and Thomas Shaft sites. The San Andreas Fault was responsible for the Great 1906 San Francisco Earthquake (Magnitude 7.8) and the 1989 Loma Prieta earthquake (Magnitude 6.9). The Hayward, Calaveras, and Greenville faults have been the location of several historic earthquakes.

Coast Ranges-Sierran Block Boundary Seismic Zone

The Coast Ranges-Sierran Block (CRSB) boundary zone, which follows the physiographic boundary between the Coast Ranges and Great Valley Geomorphic Provinces, contains potentially active “blind” faults (Wong et al., 1988). Earthquakes along the boundary between the Coast Ranges and Great Valley Geomorphic Provinces have been noted since the 1892 Vacaville-

Winters earthquake. The most recent large event along this zone is the 1983 Coalinga earthquake, which caused considerable damage in the Coalinga area, approximately 90 miles southeast of the project sites. Upon close examination, geoscientists are of the opinion that the tectonic structure and seismic activity along this seismic zone can be understood as the interaction between the Coast Ranges and the Sierran Block.

The USGS Working Group on California Earthquake Probabilities (WGCEP) has divided the CRSB boundary zone into 14 segments, identified as GV1-GV14. GV7 is defined as containing the Midway/Black Butte Fault on the west and the San Joaquin Fault on the east. The San Joaquin Fault is currently being studied (Unruh and Krug, in preparation) and is now being called the Orestimba Fault (MACTEC, 2007). This nomenclature is being used in this report.

Geologic Hazards

Earthquake Intensity Assessment

Moment or Richter magnitude is a measure of the energy released in an earthquake, and intensity is a measure of the earthquake ground shaking effects at a particular location. Intensity depends on the overall magnitude, distance to the fault, focus of earthquake energy and type of geologic materials below the area. Ground shaking effects can occur hundreds of miles from the earthquake's epicenter. Earthquakes in the Coast Ranges are expected to produce ground shaking in the San Joaquin Valley.

Ground shaking is expressed in terms of the peak ground acceleration, and as spectral acceleration at short (0.2 second) and moderately long (1.0 second) periods, as well as displacement of the ground. Areas that are underlain by bedrock tend to experience less ground shaking than those underlain by unconsolidated sediments such as artificial fill or alluvium. The composition of underlying soils in areas relatively distant from faults can intensify ground shaking. For instance, areas of the San Francisco Bay Area that experienced the worst structural damage during the 1989 Loma Prieta earthquake were not those closest to the fault, but rather those with soils that magnified the effects of ground shaking.

Fault Rupture

The four primary active faults in the San Francisco Bay region that are capable of producing fault rupture are the: San Andreas, Hayward, Northern Calaveras and Greenville (SFPUC, 2006). Fault rupture almost always follows preexisting faults, which are zones of weakness. Rupture may occur suddenly during an earthquake or slowly in the form of fault creep. Sudden displacements are more damaging to structures because they are accompanied by shaking. Fault creep is the slow rupture of the earth's crust. Faults designated as active by the CGS are those that have undergone surface displacement or seismic activity within Holocene times. None of these faults are in the vicinity of the Tesla Portal or Thomas Shaft sites, as listed in Table 4.4-1. Two faults in the western San Joaquin Valley exhibit geologic or geomorphic characteristics suggestive of Holocene or late Pleistocene activity, the San Joaquin (Orestimba) and Midway/Black Butte

faults. The potentially active faults near Tesla Portal and Thomas Shaft sites are listed in Table 4.4-2.

TABLE 4.4-1
ACTIVE FAULTS NEAR TESLA PORTAL AND THOMAS SHAFT SITES

Fault Name	Shortest Distance to Tesla Portal	Shortest Distance to Thomas Shaft	Maximum Earthquake[1]
Calaveras	26 miles	22 miles	7.25
Greenville	12 miles	8 miles	7.25
Hayward	32 miles	28 miles	7.25
San Andreas	54 miles	50 miles	8.20

Source: SFPUC (2006)

Notes: [1] The maximum earthquake magnitude is the strongest earthquake that appears capable of occurring under the currently known tectonic framework, using the Richter scale.

TABLE 4.4-2
POTENTIALLY ACTIVE FAULTS NEAR TESLA PORTAL AND THOMAS SHAFT SITES

Fault Name	Shortest Distance to Tesla Portal	Shortest Distance to Thomas Shaft	Maximum Earthquake[1]
Midway/Black Butte	1.3 miles	2.7 miles	6.3
Carnegie[2]	5.5 miles	1.5 miles	NE
Corral Hollow	5.5 miles	1.5 miles	NE
San Joaquin (Orestimba)	<1 mile	5 miles	7.2
Vernalis	12 miles	8 miles	NE

NE = not evaluated

Source: SFPUC (2006)

Notes: [1] The maximum earthquake magnitude is the strongest earthquake that appears capable of occurring under the currently known tectonic framework, using the Richter scale.

[2] A small portion of the Carnegie Fault may be considered Holocene Active (Carpenter et al., 1991). This fault has not been zoned in accordance with the Alquist-Priolo Act.

Tesla Portal Site

The fault closest to the Tesla Portal site is the San Joaquin (Orestimba) Fault, which marks the structural edge of the Coast Ranges and shows evidence of activity more than 10,000 years ago. This fault extends along the boundary between the Diablo Range and western San Joaquin Valley, and crosses the Tesla Portal site. The San Joaquin Fault is associated with late Pleistocene uplift, tilting, and folding consistent with west-side upthrust or reverse displacement (MACTEC, 2007). This fault is a "blind" structure that, during large earthquakes, produces surface folding rather than surface faulting over a zone about 300 feet wide. In the past, surface uplift, folding and faulting has occurred along the San Joaquin Fault. The Tesla Portal site is located on the up-thrown side of the fault and a large earthquake along the fault would likely cause surface deformation.

Thomas Shaft Site

The Thomas Shaft site is on the eastern edge of the San Andreas Fault system. This area contains a broad region of northwest-trending faults associated with transform faulting at the margin of the North American continental plate. Many of the small faults in the site region have not been active during Quaternary time (the past 1.6 million years). The Midway/Black Butte Fault, just east of the project site, shows no recent activity but has been active during the Quarternary time. The Carnegie-Corral Hollow Fault, starts at approximately 1.5 miles west of the project site and runs northwest. This is the nearest fault with evidence of activity during the past 10,000 years (Holocene time). Thus, this fault is considered active. In addition, the Greenville Fault, approximately 8 miles west of the project site, has been active during the past 25 years. No Holocene faults have been mapped within the project boundaries.

Liquefaction

Liquefaction is a phenomenon in which saturated granular sediments temporarily lose their shear strength during periods of earthquake-induced, strong ground shaking. The susceptibility of a site to liquefaction is a function of the depth, density, and water content of the granular sediments and the magnitude of earthquakes likely to affect the site. Saturated, unconsolidated silts, sands, silty sands, and gravels within 50 feet of the ground surface are the soil types most susceptible to liquefaction. Liquefaction-related phenomena include vertical settlement from densification, lateral spreading, ground oscillation, flow failures, loss of bearing strength, subsidence, and buoyancy effects.

Tesla Portal Site

The soils at the Tesla Portal site are comprised mainly of alluvium such as loams, clay loams, and clays washed from the Coast Ranges. Subsurface conditions at the site, where the project would be constructed, are not susceptible to liquefaction.

Thomas Shaft Site

The Thomas Shaft site is underlain by a thin layer of stiff clayey colluvium (about 5 feet thick), followed by weathered bedrock of the San Pablo Group. According to Olivia Chen Consultants (1998), “the subsurface materials underlying the project area consist of very dense rock like materials which are unlikely to liquefy during a major earthquake.”

Slope Failure

Slope failure involves the downslope displacement and movement of material, either triggered by static (i.e., gravity) or dynamic (i.e., earthquake) forces. Slope stability can depend on a number of complex variables, including the geology, structure, and amount of groundwater, as well as external processes such as climate, topography, slope geometry, and human activity.

Landslides can occur on slopes of 15 percent or less, but the probability is greater on steeper slopes that exhibit old landslide features such as scarps (surface displacement at the head of a landslide), leaning trees, and transverse ridges. Landslides typically occur within slide-prone geologic units that contain excessive amounts of water or are located on steep slopes, or where planes of weakness are parallel to the slope angle (structurally controlled).

Tesla Portal Site

The Tesla Portal site is located at the edge of the gently rolling hills of the Coast Ranges and the proposed structures associated with the Tesla Treatment Facility would be constructed on a relatively flat portion of the site. In a geotechnical report prepared by MACTEC Engineering and Consulting, Inc. (2007), potential landsliding was not identified as a geotechnical issue.

Thomas Shaft Site

The Thomas Shaft site is located in an area with gently sloping terrain, and the potential for landslides is low (CCSF Planning Department, 2007).

Mineral Resources

San Joaquin County contains a variety of mineral resources, including gravel, sand, aggregate, and clay. The principal areas of sand and gravel extraction activity in San Joaquin County are in the southwestern portion of the county in the Corral Hollow Creek alluvial fan. Most natural gas extraction activities in San Joaquin County are located in the vicinity of the Sacramento Delta, which is not near the project sites. Neither of the project sites are located in a Significant Sand and Gravel Aggregate Resource Sector, as designated by the San Joaquin County General Plan 2010 (San Joaquin County, 1992). Many areas of the state have been mapped using the California Mineral Land Classification System to identify areas with known mineral resources. This system provides guidance for identifying Mineral Resource Zones (MRZs) based on four general categories. Both project sites fall into the MRZ-1 category, which are areas where adequate information indicates that no significant mineral deposits are present, or where it is judged that little likelihood exists for their presence (CSMGB, 1983).

4.4.2 Regulatory Framework

Federal

No federal regulations pertaining to geology, soils, and seismicity were identified.

State and Local

California Public Resources Code, 1972 Alquist-Priolo Earthquake Fault Zoning Act (Amended 1994)

The Alquist-Priolo Earthquake Fault Zoning Act was passed in 1972 to mitigate the hazard of surface faulting to structures for human occupancy. In accordance with this Act, the State Geologist established regulatory zones, called "earthquake fault zones," around the surface traces of active faults and published maps showing these zones. Within these zones, buildings for human occupancy[3] cannot be constructed across the surface trace of active faults. Each earthquake fault zone extends approximately 200 to 500 feet on either side of the mapped fault trace because many active faults are complex and consist of more than one branch. There is the potential for ground surface rupture along any of the branches of the fault.

California Public Resources Code, 1990, Seismic Hazard Mapping Act

The Seismic Hazard Mapping Act was passed in 1990 following the Loma Prieta earthquake to reduce threats to public health and safety and to minimize property damage caused by earthquakes. The Act directs the California Department of Conservation to identify and map areas prone to the earthquake hazards of liquefaction, earthquake-induced landslides, and amplified ground shaking. For structures intended for human occupancy, the Act requires site-specific geotechnical investigations to identify potential seismic hazards and formulate mitigation measures prior to permitting most developments designed for human occupancy within the Zones of Required Investigation. Although the project does not include structures for human occupancy, the seismic hazard maps are useful tools for identifying areas with the potential for liquefaction and earthquake-induced landslides.

As of January 2006, 110 official seismic hazard zone maps showing areas prone to liquefaction and landslides had been published in California, and more are scheduled in the future. Most of the mapping has been performed in Southern California and the San Francisco Bay Area. Twenty-two official maps for the San Francisco Bay Area have been released, with preparation of 19 additional maps for San Mateo, Santa Clara, Alameda, and Contra Costa counties in progress or planned. The CGS has no current plans to map San Joaquin County.

Surface Mining and Reclamation Act of 1975

In accordance with the Surface Mining and Reclamation Act of 1975, the state has established a mineral land classification system to help identify and protect mineral resources in areas that are subject to urban expansion or other irreversible land uses that would preclude mineral extraction. Protected mineral resources include construction materials, industrial and chemical mineral materials, metallic and rare minerals, and nonfluid mineral fuels. The Act directs the State Geologist to classify (identify and map) the nonfuel mineral resources of the state to show where economically significant mineral deposits occur and where they are likely to occur based on the

[3] Title 14 of the California Code of Regulations, 3601(e), defines buildings intended for human occupancy as those that would be inhabited for more than 2,000 person-hours per year.

best available scientific data. Nonfuel mineral resources include: metals such as gold, silver, iron, and copper; industrial minerals such as boron compounds, rare-earth elements, clays, limestone, gypsum, salt, and dimension stone; and construction aggregate, which includes sand, gravel, and crushed stone. Many areas of the state have been mapped using the California Mineral Land Classification System to identify areas with known mineral resources. This system provides guidance for identifying Mineral Resource Zones (MRZs) based on these four general categories:

- *MRZ-1*. Areas where adequate information indicates that no significant mineral deposits are present, or where it is judged that little likelihood exists for their presence.

- *MRZ-2*. Areas where adequate information indicates that significant mineral deposits are present, or where it is judged that a high likelihood exists for their presence.

- *MRZ-3*. Areas containing mineral deposits, the significance of which cannot be evaluated.

- *MRZ-4*. Areas where available information is inadequate for assignment to any other zone.

California Building Code

The 2001 California Building Code (CBC) is based on the 1997 Uniform Building Code, with the addition of more extensive structural seismic provisions. The CBC is contained in the California Code of Regulations (CCR), Title 24, or the California Building Standards Code, and is a compilation of three types of building standards from three different origins:

- Building standards that have been adopted by state agencies without change from building standards contained in national model codes

- Building standards that have been adopted and adapted from the national model code standards to meet California conditions

- Building standards, authorized by the California legislature, that constitute extensive additions not covered by the model codes that have been adopted to address particular California concerns

Title 24, Part 2, Volume 2, Chapter 16 of the CCR contains definitions of seismic sources and the procedure used to calculate seismic forces on structures.

SFPUC General Seismic Design Requirements

The San Francisco Public Utilities Commission (SFPUC) *General Seismic Design Requirements* (SFPUC, 2006) set forth consistent criteria for the seismic design and retrofit of all facilities and components of the regional water system. In accordance with these design requirements, every project must have project-specific design criteria based on site-specific geologic and seismic hazards, including fault rupture, ground motions generated by earthquakes (ground shaking), slope instability, liquefaction, and loss of soil strength, and importance of the facility in achieving

water service delivery goals in the event of a major earthquake.[4] The design criteria are based on the referenced codes, standards, and industry publications, but would exceed these requirements for facilities that are located in a severe seismic environment and are needed to achieve water service delivery goals. Covered facilities include: offices, operating centers, water treatment plants, water storage structures, pumping plants, pipelines, tunnels, and related equipment.

4.4.3 Impacts

Significance Criteria

The City and County of San Francisco has not formally adopted significance standards for impacts related to geology, soils, and seismicity, but generally considers that implementation of a proposed project would have a significant impact if it were to:

- Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:
  - Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault (Refer to Division of Mines and Geology Special Publication 42).
  - Strong seismic ground shaking
  - Seismic-related ground failure, including liquefaction
  - Landslides
- Result in substantial soil erosion or the loss of topsoil
- Be located on geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on or offsite landslide, lateral spreading, subsidence, liquefaction, or collapse
- Be located on expansive soil, as defined in Table 18 1 B of the Uniform Building Code, creating substantial risks to life or property
- Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater
- Change substantially the topography or any unique geologic or physical features of the site

Implementation of the proposed project would have a significant impact related to mineral resources if it were to:

[4] In the General Seismic Design Requirements, the term "major earthquake" is defined as an earthquake of Richter magnitude 7.8 or larger on the San Andreas Fault, 7.1 or larger on the Hayward Fault, or 6.8 or larger on the Calaveras Fault.

- Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state

- Result in the loss of availability of a locally important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan

Areas of No Project Impact

As discussed above in the Setting section, there are no mineral resources at the project sites, and the project would have no effect on the availability of such resources. Therefore, the proposed project would have no impact with respect to these significance criteria.

The proposed project would not construct septic tanks or alternative wastewater disposal facilities at the Thomas Shaft site; therefore, this significance criterion is not applicable at the site.

Approach to Analysis

Each of the project components would be constructed in accordance with the SFPUC's *General Seismic Design Requirements* for design of New Facilities and Evaluation and Upgrade of Existing Facilities, which require a site-specific investigation and development of design criteria based on the seismic performance class of the facility and site-specific geologic and seismic hazards, including fault rupture, ground motions generated by earthquakes (groundshaking), slope instability, liquefaction, and loss of soil strength. This section analyzes geology, soils, and seismicity impacts that could occur during construction, and operational impacts associated with expansive or corrosive soils.

Construction Impacts

Impact 4.4-1: Slope instability during construction (Tesla Portal: LS; Thomas Shaft: LS)

Tesla Portal Site

The Tesla Portal site is located in an area characterized by flat to gently rolling topography underlain by geologic formations with a low potential for landslides. Grading at the site associated with the proposed project would be minimal, based on a review of current topographic maps and the footprint of planned construction. With the implementation of SFPUC Standard Construction Measure #2 (which requires a geotechnical study to identify the potential for ground failure) the impact for construction-related landsliding and slope instability is considered less than significant.

Thomas Shaft Site

The Thomas Shaft site, 4.4 miles southwest of the Tesla Portal site, is underlain by marine sandstone, mudstone, and shale of the Upper Miocene San Pablo Group, units not known to be susceptible to landsliding. This characterization is supported by geologic interpretations by Huey

(1948) and California Division of Mines and Geology (1955). Additionally, ground disturbance associated with the proposed project at this site would be restricted to construction of a shallow pipeline. With the implementation of SFPUC Standard Construction Measure #2 (which requires a geotechnical study to identify the potential for ground failure), slope instability is considered less than significant.

Impact 4.4-2: Erosion during construction (Tesla Portal: LS; Thomas Shaft: LS)

Tesla Portal Site

Project construction activities such as backfilling, grading and compaction could remove stabilizing vegetation and expose areas of loose soil that, if not properly stabilized during construction, would be subject to soil loss and erosion by wind and stormwater runoff. The project would require grading and/or excavation, although specific volumes are not available, primarily because the contract would be constructed on a Design Build basis and grading plans have not yet been developed. This could potentially result in erosion during construction. The proposed project would implement SFPUC Construction Measure #3 (onsite air and water quality measures during construction), which requires the implementation of erosion control measures. Because construction at the Tesla Portal site would result in a disturbance of over one acre of land, SFPUC must obtain coverage under the General Permit (for stormwater discharge associated with construction activity) by filing a Notice of Intent (NOI) with the State Water Resources Control Board (SWRCB) Division of Water Quality. The filing would require a Storm Water Pollution Prevention Plan (SWPPP) that would include erosion control and stormwater treatment best management practices (BMPs) to be implemented during and following construction and provide a schedule for monitoring performance. Therefore, erosion impacts during construction at the Tesla Portal site are considered less than significant.

Thomas Shaft Site

Construction activities at the Thomas Shaft site would be restricted to less than one acre and no grading is proposed. Only minimal excavation and backfilling, on the order of 50 cubic yards (cy), is proposed to install a small pipeline and percolation tank. SFPUC Standard Construction Measure #3 which includes the implementation of erosion controls at the construction site, would be required as part of the project. As mentioned above, the proposed project would require a SWPPP that would include erosion control. Erosion impacts during construction are therefore considered less than significant.

Impact 4.4-3: Substantial alteration of topography (Tesla Portal: LS; Thomas Shaft: LS)

Tesla Portal Site

The proposed improvements at the Tesla Portal site would occur on relatively flat portions of the site and cut and fill volumes would be roughly balanced onsite to avoid soil off haul or import. The maximum cut would be about 20 feet at the UV Building. The extent of fill activities would be within the 3 acres that would be graded, except areas that would be excavated for new pipeline or the electrical line for the microwave tower that would be outside the graded area. Assuming that the construction activities will be conducted in accordance with the appropriate recommendations of the site-specific geotechnical report (SFPUC Standard Construction Measure #2), substantial alteration of the topography will be a less-than-significant impact.

Thomas Shaft

No significant excavation would be conducted at the Thomas Shaft site as part of the proposed project. Since only minimal excavation would occur (approximately 50 cy), the impact associated with substantial alteration of the topography is considered less than significant.

Operational Impacts

Impact 4.4-4: Surface fault rupture (Tesla Portal: LS; Thomas Shaft: LS)

Tesla Portal Site

No Alquist-Priolo Earthquake Fault Zones are mapped near the Tesla Portal site. The San Joaquin Fault (now being called the Orestimba Fault), a blind reverse fault, is mapped along the eastern front of the Diablo Range, crossing through the vicinity of the Tesla Portal site (MACTEC, 2007). Much of the area where the proposed structures would be constructed could experience ground tilting (permanent ground deformation) of about two degrees (2°) over a distance of approximately 300 feet as a result of displacement on the San Joaquin Fault during future large earthquakes. However, surface fault rupture has not been documented on this fault.

Although the potential consequences of permanent ground deformation at the Tesla Portal site have not yet been defined, all proposed facilities would be designed and constructed in accordance with the *SFPUC General Seismic Design Requirements* (2006). In addition, as required by SFPUC Standard Construction Measure #2 (seismic and geotechnical studies), the project would incorporate recommendations by project geotechnical reports and would be designed for seismic reliability. Impacts of fault rupture are therefore considered less than significant.

Thomas Shaft Site

The nearest active or potentially active fault to the Thomas Shaft site is the Carnegie-Corral Hollow Fault, which is located about 1.5 miles west of the site. One investigation (Carpenter et al., 1991) indicates Holocene displacement along a short portion of this structure at closed landfill pit 6 on Lawrence Livermore National Laboratory property, which is located more than 1.5 miles north of the Thomas Shaft site. Therefore, a short stretch of the Carnegie-Corral Hollow Fault is considered active by the CGS (Jennings, 1994), although it is not zoned in accordance with the Alquist-Priolo Act. This fault is sufficiently far from the Thomas Shaft site; therefore, it has a low potential for surface displacement and, with implementation of SFPUC Standard Construction Measure #2, (particularly the seismic reliability design component) it is considered less than significant.

Impact 4.4-5: Seismically induced ground shaking (Tesla Portal: LS; Thomas Shaft: LS)

Although there are few active or potentially active faults within the San Joaquin Valley region, and no known active faults that cross either of the project sites, several faults in Northern California are capable of producing a large magnitude earthquake or significant ground shaking in the region. These faults include the San Andreas, Hayward, Calaveras and Greenville Faults. Depending on the level of ground shaking, an earthquake could damage the proposed buildings, pipelines, valves, and control facilities, resulting in a disruption of the proposed project treatment facility capabilities. Damage to the proposed treatment facilities could affect the ability of the SFPUC to provide treated water to its customers. To minimize potential damage to the proposed and existing facilities, the project would be designed and constructed in accordance with the SFPUC *General Seismic Design Requirements.*

Because the project facilities would be designed and constructed as per the SFPUC *General Seismic Design Requirements*, and SFPUC Standard Construction Measure #2, (particularly the seismic reliability design component) impacts related to seismic ground shaking are considered less than significant at both the Tesla Portal and Thomas Shaft sites.

Impact 4.4-6: Seismically induced ground failure, including liquefaction and settlement (Tesla Portal: LS; Thomas Shaft: LS)

Tesla Portal Site

The soils at the Tesla Portal site are comprised mainly of alluvium such as loams, clay loams, and clays washed from the Coast Ranges. Subsurface conditions at the site, where the project would be constructed, are not susceptible to liquefaction. In addition, facilities would be designed to withstand liquefaction and settlement in accordance with the SFPUC *General Seismic Design*

Requirements and SFPUC Standard Construction Measure #2, therefore, impacts related to liquefaction and other seismically induced ground failures are considered less than significant.

Thomas Shaft Site

The Thomas Shaft site is underlain by a thin layer of stiff clayey colluvium (about 5 feet thick), followed by weathered bedrock of the San Pablo Group. According to Olivia Chen Consultants (1998), "the subsurface materials underlying the project area consist of very dense rock like materials which are unlikely to liquefy during a major earthquake." In addition, the proposed facilities at the Thomas Shaft site would be designed and constructed in accordance with the SFPUC *General Seismic Design Requirements* and SFPUC Standard Construction Measure #2 Therefore, the potential for ground failure, including liquefaction and settlement, are considered less than significant.

Impact 4.4-7: Seismically induced landslides or other slope failures (Tesla Portal: LS; Thomas Shaft: LS)

Tesla Portal Site

Proposed structures at the Tesla Portal site would be located on a relatively flat portion of the site, and landslide potential has not been identified as a geotechnical issue (MACTEC, 2007). Additionally, SFPUC Standard Construction Measure #2 (seismic and geotechnical studies), would be implemented, requiring the project to incorporate recommendations by project geotechnical investigations and be designed for seismic reliability. Impacts related to seismically induced landslides or other slope failures are therefore considered less than significant.

Thomas Shaft

The project components at the Thomas Shaft site would be located in gently sloping terrain not considered susceptible to landsliding (CCSF Planning Department, 2007) and SFPUC Standard Construction Measure #2 (seismic and geotechnical studies, particularly the potential for ground failure component), would be required as part of the project. Impacts related to seismically induced landsliding or other slope failures are therefore considered less than significant.

Impact 4.4-8: Have soils incapable of adequately supporting the use of septic tanks (Tesla Portal: LS; Thomas Shaft: N/A)

Tesla Portal Site

A new septic tank and leach field to provide wastewater disposal services to the proposed buildings would be installed at the Tesla Portal site. The septic tank and leachfield would be located to the north of the new facilities beyond the area of the existing fill.

The septic system would be designed based on studies to evaluate the capacity of the native soil for leaching purposes. In addition, SFPUC Standard Construction Measure #2 (seismic and geotechnical studies) would be implemented and includes the characterization of the soils at the project site. The system would be designed in accordance with the results of the studies, therefore this impact is considered less than significant.

Impact 4.4-9: Expansive or corrosive soils (Tesla Portal: PSM; Thomas Shaft: PSM)

Tesla Portal Site

The Tesla Portal site is in an area of potentially corrosive or expansive soil. Native soils found within the project site exhibit a high shrink/swell potential and may exhibit a high risk of corrosion to concrete and uncoated steel. This would be considered a potentially significant impact. As part of SFPUC Standard Construction Measure #2 (seismic and geotechnical studies), a seismic and geotechnical study would be conducted, and recommendations implemented as part of the project. With the implementation of Mitigation Measure 4.4-9, which would characterize the extent of expansive and corrosive soils and incorporate the results of the investigation into the final project design, the impact would be reduced to a less-than-significant level. This impact is therefore potentially significant, mitigable.

Thomas Shaft

The Thomas Shaft site is in an area of potentially corrosive or expansive soil. Native soils found within the project site exhibit a high shrink/swell potential and may exhibit a high risk of corrosion to concrete and uncoated steel, which may be an issue for the new pipeline. The implementation of Mitigation Measure 4.4-9, which requires soil samples be obtained to test for corrosive/expansive characteristics and design features shall be implemented or the pipeline would apply a conservative design approach to address potential corrosivity, would reduce the impact to a less-than-significant level. This impact is therefore potentially significant, mitigable.

4.5 Hydrology and Water Quality

4.5.1 Setting

San Joaquin Region

The proposed project is located in the San Joaquin River Watershed, which has a total drainage area of approximately 15,880 square miles (RWQCB, 2007). The climate in the San Joaquin Valley is arid to semi-arid with dry, hot summers and mild winters. Summer temperatures may exceed 100ºF for extended periods of time, with no precipitation. Winter temperatures are only occasionally below freezing along the eastern margin of the valley in the Sierra Nevada foothills. The valley averages less than 10 inches of annual rainfall (RWQCB, 2006).

The San Joaquin River Watershed contains numerous water bodies (e.g., streams, rivers, and canals). Major water bodies in the region are described below.

San Joaquin River

The San Joaquin River originates from Thousand Island Lake near Mount Ritter, high on the western slopes of the Sierra Nevada. The San Joaquin River drains most of the area from the southern border of Yosemite National Park south to Kings Canyon National Park, making it the second largest river drainage in the state. The river emerges from the foothills at the former town of Millerton; Friant Dam, located on the San Joaquin River in Millerton since 1944, forms Millerton Lake. From the foothills, the river flows west to the trough of the Central Valley, where its major tributaries include the Stanislaus River, Tuolumne River, Merced River, Calaveras River, and Mokelumne River; it then flows north to the Sacramento-San Joaquin Delta. The San Joaquin River is the most notable natural water feature in San Joaquin County, and is approximately 18 miles east of the project sites.

The *Sacramento River and San Joaquin River Basin Plan* (Basin Plan) identifies the existing beneficial uses of the San Joaquin River as irrigation, stock watering, process water for industrial purposes, recreational, and freshwater and wildlife habitats. Municipal and domestic water supply is listed as a potential beneficial use (RWQCB, 2007).

Delta-Mendota Canal

The Delta-Mendota Canal is a 120-mile-long component of the Central Valley Project, a system of irrigation and hydroelectric canals and dams. The Delta-Mendota Canal is used for irrigation water. The canal runs south along the western edge of the San Joaquin Valley and ends at the San Joaquin River near the town of Mendota, just west of Fresno. The Delta-Mendota Canal is located approximately five miles east of the project sites.

The Delta-Mendota Canal is listed in the Basin Plan as having beneficial uses, including municipal and agricultural water supply, recreational, and freshwater habitat (RWQCB, 2007).

California Aqueduct

The California Aqueduct is a concrete-lined aqueduct that transports water from Northern California to Southern California. It is the main water transport structure of the State Water Project and, at nearly 450 miles in length, is the longest water channel in California. The aqueduct, built by the California Department of Water Resources, begins at the Sacramento River Delta and carries water south through the Central Valley, where it often parallels Interstate 5 (I-5). The California Aqueduct is located approximately three miles east of the project sites.

The California Aqueduct is listed in the Basin Plan as having beneficial uses, including municipal and agricultural water supply, and recreational (RWQCB, 2007).

Westside Streams

Ephemeral streams and creeks, which exist only for a short period of time following precipitation, enter the west side of the San Joaquin Valley. These streams and creeks originate on the eastern slopes of the Coast Range (also referred to as the Diablo Range in the vicinity of the project area).

Deep Gulch is located approximately one mile southeast of Tesla Portal. Deep Gulch is an ephemeral stream, and its natural drainage in the valley floor has been altered by man-made water conveyance facilities and roadways.

Corral Hollow Creek is a west side tributary of the San Joaquin River flowing west to east along the south side of Corral Hollow Road. This creek is approximately three miles northwest of the Tesla Portal site and approximately 1.5 miles north of the Thomas Shaft site. The creek is a meandering stream course with a width ranging from 8 to 12 feet (CCSF Planning Department, 2007).

Project Site Hydrology

Tesla Portal Site

The proposed facilities at the Tesla Portal site would be located on the eastern flank of the Coast Range in San Joaquin County. Surface drainages (e.g., Corral Hollow Creek) generally flow towards the east and are not well defined due to small watershed size, infrequent and/or limited precipitation, and seepage.

Stormwater runoff from the site (e.g., from rooftops of existing facilities and other existing impervious surfaces) drains to adjacent undeveloped areas. No surface runoff from the Tesla Portal site or the surrounding area discharges to the California Aqueduct or Delta-Mendota Canal or directly to Corral Hollow Creek. The site also contains an artificially-created wetland area, created from the existing facility discharge, as well as a small, unnamed ephemeral drainage feature. The artificial wetland area is approximately 0.308 acre in size and was observed to have standing water and emergent vegetation during fall 2006 site visits. The wetland delineation report was completed in May 2008 (May & Associates Inc., 2008). The water source for this area is runoff from sampling points at the existing Tesla Portal Hypochlorite Station. This area is

approximately 100 feet from the existing access road. The small, unnamed ephemeral drainage feature is approximately 1.5 feet in width at the location where the work would be performed and flows across the southern portion of the site from southwest to northeast. The ephemeral drainage was dry during site visits in winter and fall 2007 (May & Associates Inc., 2008). The primary flow sources for the ephemeral drainage include direct precipitation and surface runoff from the surrounding hills. A secondary flow source is a spillway that drains overflow water from the SFPUC system. The SFPUC surge shaft periodically releases overflow water from the Coast Range Tunnel at an elevation of 501 feet above sea level into a concrete spillway that drains to the ephemeral drainage. Neither of these two water features are listed in Section 303(d), List of Impaired Water Bodies, of the Clean Water Act, that could be affected by the proposed project at this site.

According to the *Pollution Prevention and Monitoring and Reporting Program* (PPMRP) (WA, 2006), no normally scheduled discharges occur at the Tesla Portal Valve Houses during operation of the San Joaquin Pipeline (SJPL) System. In the event of an unanticipated discharge from the SJPL System at Tesla Portal, it would flow over a large area of land and would likely dissipate and seep into the soil before reaching the nearest waterway.

Thomas Shaft Site

The Thomas Shaft site is also on the eastern flank of the Coast Range and is part of a smaller unnamed sub-watershed in the southeastern portion of the Livermore Valley. The watershed drains to the east and eventually to the San Joaquin River. Similar to the Tesla Portal site, the surface runoff at the Thomas Shaft site currently drains to open areas on the site adjacent to paved surfaces. An unnamed creek tributary, comprised of two streams, flows south to north parallel to Thomas Shaft Road. The streams, which form a tributary to Corral Hollow Creek, do not pass through the proposed project area at the Thomas Shaft site (CCSF Planning Department, 2007). No water bodies listed in Section 303(d), List of Impaired Water Bodies, could be affected by the proposed project at this site.

Groundwater

The proposed project is located in the San Joaquin River Hydrologic Region, one of three regional groundwater basins located in the Central Valley of California. Both the Tesla Portal and Thomas Shaft sites are located near the southern boundary of the Tracy Subbasin, part of the San Joaquin Valley Basin (DWR, 2003).

- The San Joaquin River Hydrologic Region groundwater basin is the source for approximately 30 percent of agricultural and urban water usage annually in the region. Aquifers generally have thicknesses of several hundred feet in the hydrologic region and frequently necessitate well depths of up to 800 feet (DWR, 2003). Unless otherwise designated by the California Regional Water Quality Control Board, all groundwater in the Central Valley region is considered to be suitable or potentially suitable, at a minimum, for municipal and domestic supply, agricultural supply, industrial service supply, and industrial process supply.

Groundwater levels near the proposed projects fluctuate depending on weather conditions and seasonal rainfall, local irrigation, and water levels in creeks. Groundwater recharge at the project

sites is likely to be limited given the prevalence of low permeability and high shrink-swell soils. According to a geotechnical report prepared by MACTEC Engineering for the SJPL System, groundwater was not encountered at the Tesla Portal project site, and is expected to be several hundred feet below the surface (MACTEC, 2007). Groundwater depth at the Thomas Shaft project site is approximately 300 to 350 feet[1] below the ground surface level. Groundwater is not currently used and is not anticipated to be used as a water supply source at either site as part of the proposed project.

Groundwater quality in the southern part of the Tracy Subbasin where the Tesla Portal and Thomas Shaft sites are located, is characterized by calcium-sodium type water. Sulfate-chloride and bicarbonate-chloride are both present in the groundwater as well. Well sampling reported mean concentrations of 463 milligrams per liter (mg/L) of dissolved solids and 1,190 mg/L of Total Dissolved Solids. Elevated levels of chloride, nitrate, and boron occur in the vicinity of the City of Tracy and in the northern and western portions of the sub-basin (DWR, 2003).

Groundwater occurs in confined, unconfined and flowing artesian conditions in the area near the Thomas Shaft site. Groundwater generally flows to the south and southeast in the southeastern and southern parts of the Lawrence Livermore National Laboratory (LLNL) Site 300, located approximately 1.5 miles north of the Thomas Shaft site, and is generally influenced by the underlying bedrock (LLNL, 1999). Monitored since 1981, most of the groundwater contamination identified has remained within the boundaries of LLNL Site 300, with the exception of two trichloroethylene (TCE) plumes, one that extends along the Corral Hollow stream bed and the second that extends approximately 200 feet off of the LLNL Site 300. The plume source is undergoing remediation, and off-site drinking water wells were reported to be unaffected by this contamination in 2005 (LLNL, 2005). Because ongoing remediation of the plume source is occurring, and the affected area is limited to 200 feet off-site from LLNL Site 300, the contamination at Site 300 is not anticipated to affect groundwater at the Thomas Shaft site.

Flooding

Flood insurance rate maps (Community-Panel Numbers 0602990715A and 0602990720A) produced by the Federal Emergency Management Agency (FEMA) (FEMA, 1980a, 1980b) for the project sites and surrounding area indicate that both sites are outside of FEMA-delineated 100-year and 500-year flood hazard zones. According to San Joaquin County's Office of Emergency Services *Dam Safety Plan*, the project sites are not within a Dam Inundation Area (San Joaquin County, 2003b).

[1] Groundwater depth at Thomas Shaft is an estimate based on regional groundwater information (LLNL, 2007). The estimate represents the most conservative elevation figure (i.e. the actual groundwater level could be much deeper) that could be extrapolated given the available information.

4.5.2 Regulatory Framework

Information is provided below for applicable federal, state, and local policies that govern hydrology, groundwater, and water quality in the project vicinity.

Federal

Clean Water Act Section 402

The federal Clean Water Act (CWA) and subsequent amendments, under the enforcement authority of the U.S. Environmental Protection Agency (U.S. EPA) and the U.S. Army Corp of Engineers, was enacted "to restore and maintain the chemical, physical, and biological integrity of the Nation's waters." The Clean Water Act gave the U.S. EPA the authority to implement pollution control programs such as setting wastewater standards for industry. The act also set water quality standards for surface waters and established the National Pollutant Discharge Elimination System (NPDES) program to protect water quality.

Under Section 402 of the CWA, discharge of pollutants to navigable waters is prohibited unless the discharge is in compliance with an NPDES permit. The U.S. EPA determined that California's water pollution control program has sufficient authority to manage the NPDES program under state law in a manner consistent with the Clean Water Act. Therefore, implementation and enforcement of the NPDES program is conducted through the California State Water Resources Control Board (SWRCB) and the nine Regional Water Quality Control Boards (RWQCBs). These agencies also implement the Waste Discharge Requirements (WDR) Program, which regulates discharges of waste to land under the California Water Code as well as discharges of waste into waters of the state that are outside federal jurisdiction, as defined under the Clean Water Act.

Clean Water Act Section 401

Section 401 of the Clean Water Act provides the SWRCB and the RWQCBs with the regulatory authority to certify, or deny any proposed federally permitted activity that could result in a discharge to surface waters of the state. To certify an activity, these agencies must find that the proposed discharge will comply with state water quality standards, including protection of beneficial uses and water quality objectives. If these agencies deny the proposed activity, the federal permit cannot be issued. This water quality certification will be required for projects involving the discharge of dredged or fill material to Waters of the U.S., as described in Section 4.6, Biological Resources.

State

Porter-Cologne Water Quality Control Act

The RWQCBs regulate water quality under the Porter-Cologne Water Quality Control Act (Porter-Cologne Act) through the regulatory standards and objectives set forth in water quality control plans (referred to as Basin Plans) prepared for each region. The Basin Plans identify

existing and potential beneficial uses and provide numerical and narrative water quality objectives to protect those uses. The Basin Plans also set forth policies to guide the implementation of programs to attain the objectives. The Central Valley RWQCB (Region #5) has regulatory authority over water bodies in the San Joaquin Region. The Central Valley RWQCB adopted its Basin Plan in 1998, and most recently revised the plan in October 2007.

Pursuant to the Porter-Cologne Act, the Central Valley RWQCB is authorized to issue permits known as "waste discharge requirements" to allow for discharge of specified quantities and qualities of waste to land or surface waters. The limitations placed on the discharge are designed to ensure compliance with water quality objectives in the Basin Plan. To obtain a permit, the discharger must submit a Report of Waste Discharge and the requirements of the California Environmental Quality Act (CEQA) must be met. The RWQCB can use this approach to regulate any discharge to surface waters. The discharger would be responsible for providing enough information regarding the chemicals and volumes to be discharged and receiving waters to allow preparation of a permit.

State Implementation of 402 NPDES Permits

As stated above, the NPDES program in California is administered by the SWRCB, with implementation and enforcement by the RWQCBs. The NPDES program, designed to protect surface water quality, is applicable to all discharges to waters of the United States, including storm water discharges associated with municipal drainage systems, construction activities, industrial operations and point sources such as wastewater treatment plant discharges, water conveyance system blow-offs and other discharges to water bodies. In general, the NPDES permit program is designed to control, minimize, or reduce surface water impacts from point source discharges.

Construction Stormwater NPDES Permit

The federal Clean Water Act prohibits discharges of stormwater from construction projects unless the discharge is in compliance with an NPDES permit. The SWRCB has adopted a Statewide General Permit for Stormwater Discharges Associated with Construction Activity (General Permit) that encompasses one or more acres of soil disturbance (SWRCB, 1999). Construction activity includes clearing, grading, excavation, stockpiling, and reconstruction of existing facilities involving removal or replacement. In general, the NPDES stormwater permitting requirements for construction activities require that the landowner and/or contractor submit a notice of intent (NOI) and develop and implement a stormwater pollution prevention plan (SWPPP). The SWPPP includes a site map or maps showing the construction site perimeter, existing and proposed buildings, lots, roadways, stormwater collection and discharge points, general topography both before and after construction, and drainage patterns across the site.

The SWPPP must also specify best management practices (BMPs) that will be used to protect stormwater runoff as well as the placement of those BMPs; a visual monitoring program; a chemical monitoring program for non-visible pollutants to be implemented if there is a failure of BMPs; and a sediment monitoring plan if the site discharges directly to a water body listed as an

impaired water body for sediment. Measures for erosion and sediment control, construction waste handling and disposal, and post-construction erosion and sediment control must also be addressed, along with methods to eliminate or reduce non-stormwater discharges to receiving waters. The SWRCB is in the process of reissuing the Construction General Permit and released a preliminary draft of the new permit on March 2, 2007 (SWRCB, 2007). If adopted, this permit will replace the 1999 Construction General Permit, and, as proposed, may require the permittee to implement additional minimum BMPs as well as specific analytical procedures to determine whether the BMPs implemented on a construction site are: (1) preventing further impairment to waters listed as impaired for sediment or silt due to sediment in stormwaters discharged directly into such waters; and (2) preventing non-visible pollutants in stormwater discharges from construction sites from causing or contributing to exceedances of water quality objectives. In addition, all sites would be required to meet new development and redevelopment performance standards to minimize or mitigate hydromodification impacts. As proposed, the permit allows for a risk-based permitting approach and specifies water quality action levels, numeric effluent levels, and detailed management practices. Under the new permit, the SWPPP must be prepared or have preparation overseen by a qualified SWPPP developer; the SWPPP would be much more limited and would be meant to demonstrate compliance with the detailed permit requirements, with less discretion in how these requirements are met. The permit would also enable public review and hearings on permit applications. The new permit, as proposed, would also establish new procedures for SWPPP preparation as well as public participation in the permit process. According to the SWRCB, a new draft of the Construction General Permit has been released for a second round of public review from March 2008 to June 2008, and is not anticipated to be implemented until fall 2008 at the earliest. In addition, many of the new requirements (including the SWPPP preparation) may not be phased in or implemented until after the permit is approved. (SFPUC personal communication with SWRQCB, January 2008). The new Construction General Permit is expected to have different requirements; however, it is unclear whether it will be in place and applicable by the time of project approval.

Project construction at the Tesla Portal site would disturb more than one acre of soil and, therefore, would be subject to NPDES permitting. The Thomas Shaft site would require less than an acre of soil disturbance and would not be subject to NPDES permitting.

Waste Discharge Requirements General Order for Dewatering and Other Low-Threat Discharges to Surface Waters

Under the terms of a general permit, the Central Valley RWQCB allows the discharge to waters of the United States of certain categories of clean or relatively pollutant-free wastewater posing little or no threat to water quality. The general permit is Order No. 5-00-175, NPDES No. CAG995001, Waste Discharge Requirements General Order for Dewatering and Other Low Threat Discharges to Surface Waters (RWQCB Order No. 5-00-175). The permit covers water supply system discharges provided that they do not contain significant quantities of pollutants and either: (1) the discharge is 4 months or less in duration, or (2) the average dry weather discharge does not exceed 0.25 million gallons per day (mgd). These wastewaters may be produced and treated on a continuous or batch basis (SWRCB, 2000). All pollutants must be properly treated

prior to discharge to ensure continuous compliance with applicable water quality requirements. Chlorine and other constituents normally found in these discharges must be removed to provide protection of downstream beneficial uses, including fish and other aquatic life. Multiple discharges may be considered together as one project. Compliance with RWQCB Order No. 5-00-175 serves as compliance with NPDES permit requirements pursuant to Section 402 of the CWA and amendments thereto. The PPMRP for the Hetch Hetchy water supply system facilities (WA, 2006) is designed to achieve compliance with the requirements of RWQCB Order No. 5-00-175. The PPMRP covers existing discharges of Tesla Portal water, which are expected to seep into the ground or evaporate before reaching surface waters. The proposed project may eliminate this method of discharge by directing blow-offs and process water to the proposed containment basin, unless an unanticipated event occurs. The PPMRP would be revised accordingly.

Statewide General Waste Discharge Requirements for Discharges to Land with a Low Threat to Water Quality

The SWRCB has issued the Statewide General Waste Discharge Requirements for Discharges to Land with Low Threat to Water Quality (Order No. 2003-003-DWQ) to regulate discharges to land that are considered to have a low threat to water quality. Categories of covered discharges include wastes from the installation of borings and wells, clear water discharges, small dewatering projects, and miscellaneous discharges. In accordance with this permit, all dischargers must comply with all applicable Basin Plan provisions, including any prohibitions and water quality objectives governing the discharge. In addition, the discharge of waste may not cause the spread of groundwater contamination. Discharges must be made to land owned or controlled by the discharger, unless the discharger has a written lease or agreement with the landowner.

Similar to the NPDES program, dischargers seeking coverage under this permit must submit an NOI to comply with the terms and conditions of this general permit or a report of waste discharge, fees, a project map, evidence of CEQA compliance, and a discharger monitoring plan. The plan must include a list of all pollutants believed to be present in the discharge, the approximate concentration of pollutants in the discharge, monitoring locations, monitoring frequencies, and a reporting schedule. Discharges to land listed as a hazardous materials site are not eligible for coverage under this general permit. In addition, discharges that could have a significant impact on biological resources, cultural resources, aesthetics, or air quality, or that could significantly alter the existing drainage pattern of a discharge site or surroundings are not eligible for coverage. Other discharges not covered under this permit are those that would significantly physically divide an established community, significantly conflict with any applicable land use plan, policy, or regulation of an agency, or significantly conflict with any applicable habitat or community conservation plan.

At the Tesla Portal site, the water to be discharged to the containment basin would be raw water containing no chlorine, but with a pH adjustment to 9.2. At the Thomas Shaft site, the water discharged through the percolation tank will have chlorine residual from chlorination at Tesla Portal. Both discharges would require coverage under Order No. 2003-003-DWQ.

California Fish & Game Code

The California Department of Fish and Game (CDFG) has jurisdiction over any activity that could affect the bank or bed of any stream that has value to fish and wildlife. If any changes are proposed along a creek or waterway within its jurisdiction, a streambed alteration agreement would be required under California Fish and Game Code Section 1602. Refer to Section 4.6, Biological Resources, for additional information.

Local

Plans and policies of the City and County of San Francisco (CCSF) pertaining to hydrology, groundwater, and water quality apply to the proposed project. Section 4.2 describes the CCSF policies that apply to the proposed project. Because the project sites are in San Joaquin County, local policies apply directly to the project as described below.

San Joaquin County

In San Joaquin County, stormwater management issues, erosion and watercourse protection, and construction-related permits for stormwater and erosion protection are managed through the Department of Public Works.

The San Joaquin County General Plan, Volume 1, Chapter IV – Community Development includes policies concerning wastewater treatment, which at a minimum, require rural developments to have a septic system for wastewater treatment. The Community Development chapter also establishes policies concerning stormwater drainage. The policies require a public drainage system in new developments as well as the consideration of stormwater use for replenishment of the groundwater basin if the water is of safe quality. Volume 1, Chapter VI – Resources of the General Plan also mandates that water quality shall meet the standards necessary for the uses to which the water resources are put and shall be protected and improved where necessary (San Joaquin County, 1992).

Wastewater discharges must comply with the General Requirements for Wastewater Disposal found in San Joaquin County Development Title Chapter 9-1105, Section 9-1105.2, and Chapter 9-1110 (San Joaquin County, 1995). Individual sewage disposal system permitting requirements, as required by Chapter 9-1110, are described in the Environmental Health Department's *Onsite Wastewater Disposal Standards* (San Joaquin County, 2003a). Septic tanks must be at least 100 feet from public wells and 50 feet from all other wells. Similarly, seepage pits and sewage ponds must be at least 150 feet from public wells and at least 100 feet from all other wells. San Joaquin County Ordinance Chapter 9-1125.3 also states that waste shall not be discharged within 150 feet of a waterway, which would require the leachfield to be at least 150 feet away from the artificial wetland.

4.5.3 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to hydrology and water quality, but generally considers that implementation of a proposed project would have a significant impact if it were to:

- Violate any water quality standards or waste discharge requirements
- Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of preexisting nearby wells would drop to a level that would not support existing land uses or planned uses for which permits have been granted)
- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on or off the site
- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on or off the site
- Create or contribute runoff water that would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff
- Otherwise substantially degrade water quality
- Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary, Flood Insurance Rate Map, or other authoritative flood hazard delineation map
- Place within a 100-year flood hazard area structures that would impede or redirect flood flows
- Expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam
- Expose people or structures to a significant risk of loss, injury, or death involving inundation by seiche, tsunami, or mudflow

Areas of No Project Impact

Several of these criteria are not applicable to the proposed project, as there either is no potential for the impact to occur, or the applicable environmental resource does not occur within the study area or the area of potential effect. Neither of the project sites is within an area identified as a

100-year flood hazard area, or within a Dam Inundation Area, and no levees or dams are in proximity to the sites. In addition, the project does not propose to construct any new housing. The absence of any oceans, seas, or large lakes in the project vicinities precludes the possibility of inundation by seiche or tsunami. The absence of shallow groundwater at either of the project sites would preclude the need for dewatering during project construction. No depletion of groundwater would take place as neither site includes groundwater pumping activities or uses groundwater as a water supply. Therefore, the proposed project would have no impact with respect to these significance criteria.

At the Thomas Shaft site, proposed project activities include the installation of a percolation tank, a 360-square-foot prefabricated structure, and minor trenching, and no construction activities (e.g., tie-ins) are proposed at this site that would require any discharge of treated water. Therefore, water quality is not anticipated to be degraded as a result of any construction-related discharges of treated water, and the impact would not be applicable. Additionally, the proposed facilities at the Thomas Shaft site would not alter drainage at the site. No new impervious surface would be created as a result of the project; therefore, potential water quality impacts would not be applicable.

Approach to Analysis

The hydrology and water quality analysis evaluates short-term and long-term impacts associated with the potential for water quality degradation and increased erosion, as well as runoff attributed to the construction and operation of the proposed facilities at the Tesla Portal and Thomas Shaft sites. In general, implementation of the proposed project would not have significant direct long-term or short-term effects on the hydrology or water quality of regional and local surface waters, given compliance with existing regulations and established project procedures.

Construction Impacts

Impact 4.5-1: Degradation of water bodies as a result of erosion and sedimentation or a hazardous materials release during construction (Tesla Portal: LS; Thomas Shaft: LS)

Tesla Portal Site

Construction-related erosion could result from alterations in drainage patterns and grading activities, and could increase sedimentation in receiving waters. Sedimentation can lead to a reduction of water quality because sediment can carry nitrogen, phosphorus, and trace metals. The increase in sedimentation could accumulate in the artificial wetland and unnamed ephemeral drainage on the Tesla Portal project site. In addition, the temporary storage of diesel and use of construction equipment could accidentally release construction-related chemicals, such as oil and fuel, which could degrade the water quality of the wetland and unnamed ephemeral drainage on the project site.

Earthwork and grading activities would occur over portions of the project site. Vegetative cover, which acts to stabilize the soil, would be removed from areas where earthwork and grading activities would occur, which would present a threat of soil erosion from soil disturbance by subjecting unpaved and unvegetated areas to the erosional forces of runoff. However, the majority of the Tesla Portal site would remain undeveloped.

The proposed project would include SFPUC Construction Measure #3 (onsite air and water quality measures during construction), which requires the implementation of erosion control measures. Since the Tesla Portal site would result in a disturbance of over one acre of land, SFPUC must obtain coverage under NPDES General Permit (for stormwater discharge associated with construction activity) by filing an NOI that includes the preparation of a SWPPP and a Monitoring Program, with the SWRCB Division of Water Quality. The filing would describe erosion control and stormwater treatment BMPs to be implemented during and following construction and provide a schedule for monitoring performance. These BMPs would serve to control point and non-point source pollutants in stormwater and are a component of the project's SWPPP for construction activities. The SWPPP would include several BMPs for preventing the discharge of other non-point source pollutants besides sediment (such as paint or concrete) to downstream waters. These practices would include a provision requiring the placement of drip pans underneath heavy equipment that is stored overnight to prevent leaks of hydraulic fluids, oil, grease, or fuels from reaching an adjacent waterway.

The SWPPP would also include protection measures for the temporary onsite storage of diesel fuels used during construction, including requirements for secondary containment and berming of the diesel storage area or any chemical storage areas to contain a potential release and to prevent any such release from reaching an adjacent waterway (e.g., artificial wetland or ephemeral drainage). Monitoring would be conducted to ensure that all BMPs are implemented, maintained, and effective.

In addition, the proposed project will implement SFPUC Standard Construction Measure #10, which stipulates that the construction contractor will return the project site to its general pre-construction condition, including regrading the site and revegetating disturbed areas.

Given the relatively small area of impact (disturbed areas) anticipated at the project site, the implementation of SFPUC Construction Measures #3 and #10, compliance with NPDES General Permit requirements, and preparation of a SWPPP, impacts related to the degradation of water bodies as a result of erosion, sedimentation, or hazardous material releases during construction would be less than significant.

Thomas Shaft Site

Proposed project construction would be conducted on less than one acre, and would include only minor trenching. Construction activities would not be conducted near any surface water feature and would not require coverage under the NPDES General Permit. The proposed project would include SFPUC Construction Measures #3 and #10, which would incorporate erosion control

measures as necessary and return the project site to its general pre-construction condition. Therefore, impacts related to the degradation of water bodies as a result of erosion, sedimentation, or hazardous materials releases during construction at the Thomas Shaft site would be less than significant.

Impact 4.5-2: Degradation of water quality due to construction-related discharges of treated water (Tesla Portal: LS; Thomas Shaft: N/A)

Tesla Portal Site

The construction and installation of new facilities at the Tesla Portal site have the potential to discharge treated water. In particular, the installation of two new valve vaults and valve houses at the site could potentially discharge large volumes of water from the existing SJPLs. However, construction activities related to the tie-in at the Tesla Portal valve houses would be planned to coincide with and be completed within the planned shutdown period from January to February. Therefore, there would be no discharge associated with the project, because work is scheduled during this shutdown period and SJPLs involved would not be in service. This impact would be less than significant.

Operational Impacts

Impact 4.5-3: Degradation of water quality and increased flows due to discharges to surface water or groundwater during operation (Tesla Portal: LS; Thomas Shaft: LS)

Tesla Portal Site

The new Tesla Treatment Facility would contain three 16,000-gallon sodium hypochlorite tanks, three two 10,000-gallon fluoride tanks, two 12,500-gallon carbon dioxide (CO_2) tanks, and various treatment chemicals. A spill control system would be installed and implemented to prevent discharge of chemicals to surface water, groundwater, or wetlands.

The new septic tank and leachfield to the east of the new buildings would be designed to comply with county ordinances and wastewater disposal standards addressing minimum distances between waste discharges and surface water. The tank and leachfield would be at least 150 feet from waterways per San Joaquin County ordinance Chapter 9-1125.3. Because the proposed tank and leachfield would be in compliance with these regulations, any discharge impacts to nearby waterways would be minimized and this impact would be less than significant.

During operation, the proposed Tesla Treatment Facility would be expected to require miscellaneous discharges related to maintenance or emergencies, similar to existing conditions. Currently, these discharges at the existing Tesla Portal site are covered under the PPMRP in

accordance with RWQCB Order No. 5-00-175. Discharges from the existing site are anticipated to have a residual chlorine level ranging from 2.0 to 0.75 mg/L. Any discharge from the existing site must sheet flow over a relatively flat field, during which chlorine would dissipate. Residual chlorine is anticipated to dissipate quickly with exposure to light, increased temperature, and agitation. All or most of the water is expected to infiltrate into the ground or evaporate before reaching the nearest waterway, an un-named tributary of Deep Gulch, approximately three-quarters mile away (WA, 2006). Water from blow-offs at the new facility is anticipated to have quality similar to the existing discharge. The water would be discharged via the proposed percolation and evaporation from the 90,000-gallon containment basin (percolation pond). The basin would be lined with riprap to capture released water for grit removal and periodic maintenance, which entails a blow-off on the order of 10,000 gallons three times per month. These discharges would require coverage under SWRCB Order No. 2003-003-DWQ.

The groundwater is not anticipated to be affected by percolation because the groundwater level at Tesla Portal is expected to be several hundred feet below ground surface (bgs) (MACTEC, 2007). Consequently, the discharged water is not anticipated to decrease the quality of groundwater. Therefore, this impact would be less than significant.

Thomas Shaft Site

The proposed project includes the construction of a percolation water tank with an approximate capacity of 2,500 gallons at the Thomas Shaft site. The tank would contain approximately 12 to 18 inches of crushed rock at the bottom rather than being sealed to allow percolation of process water. The process water used for sampling chlorine residual, pH, and turbidity of water at the Thomas Shaft site would be discharged through this tank. This discharge would be covered under SWRCB Order No. 2003-003-DWQ, which would require compliance with all applicable Basin Plan provisions and discharge to land owned or controlled by SFPUC. Compliance with Order No. 2003-003-DWQ also requires dischargers to submit an NOI to comply with the terms and conditions of this general permit or a report of waste discharge, fees, a project map, evidence of CEQA compliance, and a discharge monitoring plan.

At the Thomas Shaft site, the percolation of the process water has the potential to affect groundwater quality. However, the groundwater level is at a depth of approximately 300 to 350 feet bgs, and process water would not percolate to a depth as great as 300 bgs. Therefore, impacts from the Thomas Shaft facilities discharges would be less than significant.

Impact 4.5-4: Degradation of water quality as a result of alteration of drainage patterns or an increase in impervious surfaces (Tesla Portal: LS; Thomas Shaft: N/A)

Tesla Portal Site

Construction of the proposed project would result in the alteration of existing drainage patterns and would result in the conversion of approximately 3 acres of pervious surface area to impervious surface area. This amount of new impervious surface area is considered a minor increase given the amount of surface area that would remain pervious on the 52-acre project site. Nevertheless, the increase of impervious surfaces with resultant higher peak flow runoff rates and velocities could result in onsite and offsite erosion, and an incremental increase in runoff volume and related stormwater pollutants is anticipated.

During the life of the proposed project, non-point source pollutants would be the primary contributors to potential water quality degradation. Non-point source pollutants would be washed by rainwater from roadways and rooftops into onsite drainage networks (e.g., in the form of sheet flow runoff from paved surfaces) and eventually to a discharge point such as the site's unnamed ephemeral drainage or the artificial wetland feature. Potential non-point source pollutants include oil, grease, and heavy metals from automobiles, and petroleum hydrocarbons from fuels.

At the Tesla Portal site, SFPUC and its contractors would be required to implement SFPUC Construction Measure #10, which requires the return of each project site to the general condition that existed prior to construction. This would include regrading the site and revegetating disturbed areas, which would ensure that drainage patterns are not altered in a way that could cause erosion or sedimentation. In addition, the proposed project facilities at the Tesla Portal would be required to implement permanent erosion control measures in compliance with applicable water quality regulations (e.g., the General Permit). Additionally, post-construction stormwater controls would be implemented and maintained, as specified in the project site's SWPPP. Given the water quality management features described above, impacts at the Tesla Portal site related to increases in surface runoff, stormwater pollutants, and the potential for onsite and offsite erosion would be less than significant.

4.6 Biological Resources

This section is based on two technical reports prepared by May & Associates, Inc. (May & Associates) in 2008: *San Joaquin Regional Water Quality Improvement Project Biological Resource Report*, May 2008 (Biological Resources Report), and *Delineation of Waters of the United States and Waters of the State, San Joaquin Regional Water Quality Control Project*, May 2008 (Wetland Delineation).

4.6.1 Setting

Habitats

Plant communities for the project sites are classified according to a combination of classification systems, including the Preliminary Descriptions of the Terrestrial Natural Communities of California (Holland, 1986) and A Manual of California Vegetation (Sawyer and Keeler-Wolff, 1995). A description of the habitats/vegetation located on the Tesla Portal and Thomas Shaft project sites is provided below and illustrated in Figure 4.6-1, Tesla Portal Vegetation Map, and Figure 4.6-2, Thomas Shaft Vegetation Map.

California Annual Grassland

California annual grassland is the predominant natural community at the project sites. At the Tesla Portal site, there is approximately 42 acres of California annual grassland, and about 25.6 acres of California annual grassland at the Thomas Shaft site. This natural community is dominated by non-native annual grasses such as soft chess *(Bromus hordeaceous)*, Italian ryegrass *(Lolium multiflorum)*, wild oats *(Avena fatua)*, ripgut brome *(Bromus diandrus)*, foxtail barley *(Hordeum murinum)*, and weedy annual and perennial forbs including as storksbill *(Erodium* spp.*)*, wild radish *(Raphanus sativus)*, charlock *(Sinapis arvensis)*, and cut leaved geranium *(Geranium dissectum)* (Sawyer and Keeler-Wolf, 1995). The majority of the California annual grassland in the study area[1] is somewhat disturbed/ruderal in character, perhaps due to past land use practices.

Ruderal/Disturbed Areas

Ruderal and disturbed areas are common in the project areas. Ruderal habitat is defined as a habitat where disturbance is sustained but where there is no intentional substitution of vegetation. At the Tesla Portal site, approximately 9.4 acres is ruderal or disturbed, and 2.4 acres at the Thomas Shaft site is ruderal or disturbed. These areas have been substantively disturbed over time such that native vegetation is either completely lacking, or is ruderal in nature. Disturbed areas include dirt and gravel roads, paved surfaces, and graded areas. Weedy species observed in

[1] The project "study area" refers to the area surveyed in the biological resources surveys conducted for this project. At the Tesla Portal project site, the study area is the same as the property boundary. The Thomas Shaft study area includes the Thomas Shaft facility, as well as the immediately adjacent lands.

Thomas Shaft Vegetation Map

Figure 4.6-2

these areas include fennel *(Foeniculum vulgare)*, Italian thistle *(Carduus pycnocephalus)*, wild radish *(Raphanus sativus)*, and bristly ox tongue *(Picris echioides)*.

Artificial Wetland

There is an artificial wetland area in the upland habitat at the Tesla Portal site that is approximately 0.308 acre in size. It was created and is currently sustained by water from the existing Tesla Portal Hypochlorite Station facility and has no downstream connection to a drainage or waterbody. The wetland is dominated by a wide variety of hydrophytic vegetation such as rabbitsfoot grass *(Polypogon monspeliensis)*, umbrella sedge *(Cyperus esculentus)*, cudweed *(Gnaphalium* sp.*)*, Baltic rush *(Juncus balticus)*, dallis grass *(Paspalum dilatatum)*, cocklebur (*Xanthium strumarium)*, willow herb (*Epilobium* spp.*)*, and narrow leaved cattail *(Typha angustifolia)*. Pacific chorus frogs *(Pseudacris regilis)* were observed in the wetland during the 2007 site assessment. A wetland delineation of the artificial wetland area at the Tesla Portal site was verified by the U.S. Army Corps of Engineers (USACOE) in 2001 (LSA, 2001). The wetland delineation verified that the artificial wetland is a non-jurisdictional feature. A follow-up wetland delineation and evaluation was conducted in 2007 by May & Associates and, based on observed field condition; it was again determined to be a non-jurisdictional wetland that was created in an upland pursuant to Section 404 of the Clean Water Act. This wetland is maintained by an artificial water source (i.e., water discharges from the existing Tesla Portal Hypochlorite Station for water quality testing) and does not have any natural hydrologic connection to a traditionally navigable waterway.

Since the wetland is supported by artificial water sources and was created in an upland, and has been used primarily as a result of water treatment purposes it is also unlikely that the feature would be considered jurisdictional "Waters of the State" pursuant to the State Regional Water Quality Control Board's definition of such features (i.e., isolated wetlands) under the Porter Cologne Water Quality Control Act. However, the wetland's non-jurisdictional status pursuant to this state authority is considered preliminary at this time. Regardless, this artificial wetland does provide habitat values to dependent plant and wildlife species such as a year-round source of drinking water in an otherwise arid valley and, therefore, is considered a sensitive biological resource. The artificial wetland may also provide habitat for a variety of other wetland-associated species and, because it is within a grassland community, can be particularly important. A variety of wetland-associated birds, including red-winged blackbirds, marsh wren, and several species of waterfowl and other waterbirds could also use the site for food and cover.

Ephemeral Drainage

There is also an ephemeral drainage that is approximately 5 to 10 feet wide (measured from top-of-bank to top-of-bank) in the southwest end of the Tesla Portal site. However, within the proposed project construction area, the drainage averages 1.5 feet in width, and flows from the southwest to the northeast across the site. Approximately 1,420 linear feet of the ephemeral drainage is found on the Tesla Portal site. The ephemeral drainage was dry during the May & Associates' February 2007 reconnaissance survey, as well as during the wetland delineation conducted in September 2007. The primary hydrologic sources for the ephemeral drainage

include direct precipitation and surface runoff from the surrounding hills. An emergency spillway also leads to the ephemeral drainage within the study area, and there is evidence immediately below the spillway indicating that some flow has entered the ephemeral drainage. The upper end of the ephemeral drainage is shown on a United States Geological Survey (USGS) map as a blue line stream; however, field observations do not indicate flow of sufficient volume or duration to support this mapping designation in the study area.

At its downstream end near West Vernalis Road, water collecting in the ephemeral drainage is channeled under West Vernalis Road through a road culvert, and then diverted into a roadside ditch. The roadside ditch has no downstream connection to a drainage or water body, and water entering into the ditch is likely to sheet-flow into a nearby field, across from the Chrisman residential subdivision adjacent to Stearman Court (refer to Figure 4.3-1a).

Vegetation in the ephemeral drainage is predominantly upland grasses. Dominant species include soft chess *(Bromus hordeaceous)*, hare barley *(Hordeum murinum)*, and wild oats (*Avena fatua)*, with occasional forbs such as turkey mullen *(Eremocarpus setigerus)* and vinegar weed *(Tricostema lanceolatum)* present during summer months. The native shrub, gumplant *(Grindelia camporum* ssp. *parviflorum)* occasionally occurs in and near the channel bottom. Vegetation within the ephemeral drainage is very similar to that found in the adjacent upland grassland habitats, suggesting that the period that water is present is likely of a very short duration.

The Wetland Delineation concluded that the ephemeral drainage is not a jurisdictional "Waters of the United States" feature pursuant to Section 404 of the Clean Water Act because it is an isolated water body (i.e., lacks a connection to a downstream waterway, does not appear to be used for intrastate recreation or commerce, or is a tributary and are directly connected to such areas). The ephemeral drainage is, however, considered a potential jurisdictional "Waters of the State" because its upstream extent, although outside of the study area, was mapped as a blue line stream on USGS topographic maps. SFPUC is working with the regulatory agencies to determine the State's jurisdiction over the drainage. Further, although this is an isolated drainage feature, it does convey natural flow for part of the year. Because water is present for a very short duration, vegetation is similar to the surrounding grassland community, and there are no unique features associated with the drainage. Wildlife use of the ephemeral drainage is likely similar to the surrounding grasslands.

Sensitive Natural Communities

Sensitive natural communities in the San Joaquin Region are found in areas of extensive natural habitat, such as the eastern and western foothills of the San Joaquin Valley, and near the San Joaquin River floodplain. Sensitive natural communities known to occur in the greater San Joaquin County Region include: Valley needlegrass grassland and pine bluegrass grassland, Northern hardpan vernal pool, Alkali meadow, Coastal and valley freshwater marsh and various riparian communities. None of these sensitive natural communities were identified on the project sites.

Special Status Species

For the purposes of this EIR, special-status species and sensitive communities are defined as follows:

- Plants and wildlife that are listed or proposed for listing as threatened or endangered or rare (for plants) under the California Endangered Species Act (Fish and Game Code 1992 Sections 2050 et seq.; 14 CCR Sections 670.1 et seq.) and/or the Federal Endangered Species Act (50 CFR 17.11 for wildlife; 50 CFR 17.12 for plants; and various notices in the Federal Register [FR] for proposed species)
- Plants and wildlife that are candidates for possible future listing as threatened or endangered under the Federal Endangered Species Act (50 CFR 17.12 for plants; 61 FR 7591, February 28, 1996 for wildlife) and under the State Endangered Species Act
- Plants and wildlife that meet the definition of rare or endangered under CEQA (14 CCR Section 15380), but are not included on state or federal endangered species lists
- Plants occurring on List 1A, List 1B, and List 2 of the California Native Plant Society's (CNPS) Inventory of Rare and Endangered Plants of California. The California Department of Fish and Game (CDFG) recognizes that Lists 1A, 1B, and 2 of the CNPS inventory contain plants that, in the majority of cases, would qualify for state listing, and the CDFG requests their inclusion in EIRs, as necessary
- Communities designated by the CDFG as significant natural communities
- Wildlife that is designated as "Species of Special Concern" by the CDFG
- Wildlife that is a "fully protected" species under the California (Fish and Game Code, Sections 3511, 4700, 5050 and 5515)
- Animals on the Special Animals list maintained by the CDFG

Special Status Plant Species

A total of 48 special-status plants were initially evaluated for potential to occur within the vicinity of the project sites, based on proximity to known occurrences (CNDDB 2006, USFWS 2007) and on results of 2003 botanical surveys conducted at Thomas Shaft by Weiss and Associates (Weiss Associates, 2003), 2004 botanical surveys at Thomas Shaft conducted by Tetra Tech (Tetra Tech 2004a), and the 2006 surveys of Tesla Portal (URS-ATS Joint Venture, 2008; May & Associates, 2008a). Refer to Appendix C, Special-Status Plant Species Initially Evaluated, for more detailed information regarding the special-status plant species initially considered.

Special-status plant species were assessed for potential to occur based on similarity of habitats present at the project sites to the habitats known to support the species and surveys conducted on the Thomas Shaft site and the Tesla Portal site (Tetra Tech, 2004a; URS-ATS Joint Venture, 2008). The project sites support habitat with potential to support 17 of the 48 sensitive plant species considered. Plant species considered with potential to occur at one or both sites are listed

in Table 4.6-1, Special Status Plant Species Potentially Found Onsite[2]. Despite the presence of suitable habitat at the project sites, no special-status plant species were detected at either the Tesla Portal site or the Thomas Shaft site during site surveys (Weiss Associates, 2003; Tetra Tech, 2004a; URS-ATS Joint Venture, 2008; May & Associates, 2008a, Tetra Tech 2008). One special-status species, Mt Diablo cottonweed, was observed along the access road leading to the Thomas Shaft site, but is not located within the project footprint or construction staging area (Weiss Associates, 2003). The remaining 31 special-status plant species originally considered were determined unlikely to occur because the project sites lack suitable habitats to support them. Specifically, the project area lacks the following habitats and site conditions:

- Vernal pools and seasonal wetlands
- Alkaline soils, seasonal alkaline wetlands, alkaline playas, or chenopod scrub
- Riverine habitats including, creeks, streams, canals, and other permanent waterways
- Sloughs, riverbanks, marshes (freshwater or brackish) and swamps
- Oak woodlands
- Riparian woodlands
- Chaparral
- Coniferous forests, closed-cone pine forests, pinyon-juniper woodlands, upland broadleaf coniferous forests and redwood forest

Special Status Wildlife Species

A total of 36 special-status wildlife species were initially evaluated for potential to occur on or within the vicinity of the Tesla Portal and Thomas Shaft sites. The Tesla Portal and Thomas Shaft sites support suitable habitat for 18 of the 36 special-status wildlife species, and of the 18 species with suitable habitat present at the sites, seven special-status wildlife species are either reported to

occur onsite (Tetra Tech, 2004b, c, d, e, and f); or were directly observed onsite during the 2003 field surveys (Weiss, 2003) or the 2006-2007 May & Associate's site assessment. The 36 special-status wildlife species initially evaluated as well as the species with suitable habitat present at the project sites are presented in Appendix C, Special-Status Wildlife Species Initially Evaluated. Several of these species have low potential to occur on the project sites due to marginal habitat conditions.

Of the 36 special-status wildlife species originally considered, 18 species were determined unlikely to occur at the project sites for one or more of the following reasons:

- Project study area lacks suitable habitat characteristics
- Project study area supports degraded or low quality habitat
- Habitat within the project study area is not unique within the larger landscape, and the species has a limited distribution
- Project area is outside the known range of the species

The project sites contain suitable foraging and/or breeding habitat for 18 special-status wildlife species known to occur, or with potential habitat present at the project sites. Table 4.6-2, Special Status Wildlife Species Potentially Found Onsite[3], illustrates the special status wildlife species and/or habitat potentially found on the project sites.

Eight of the 18 special-status wildlife species have potential to breed within the project sites, including the California horned lark, Swainson's hawk, white-tailed kite, burrowing owl, San Joaquin pocket mouse, San Joaquin whipsnake, San Joaquin horned lizard and San Joaquin kit fox. Raptor species (e.g., prairie falcon, white-tailed kite, northern harrier, Swainson's hawk, ferruginous hawk, golden eagle and burrowing owl) that are known or have potential to forage on the sites are not known to nest onsite. Further, with the exception of several mature pepper trees and the eucalyptus trees bordering existing structures at the Tesla Portal site, suitable raptor nesting habitat (i.e., large trees and snags) is largely absent within the project sites and is limited on lands immediately surrounding the Thomas Shaft and Tesla Portal sites.

The following discussion details the presence or absence of special status wildlife species on the project sites, as well as the presence or absence of suitable foraging and/or breeding habitat for special status wildlife species on the sites:

California Red-Legged Frog and California Tiger Salamander. Neither the Thomas Shaft or Tesla Portal sites support potential breeding habitat for the California red-legged frog or California tiger salamander. The artificial wetland on the Tesla Portal site is considered unsuitable as a potential breeding location for either species due to the high level of disturbance,

[3] Note Table 4.6-2 differs from Table C-2 presented in Appendix C. Table C-2 evaluates special-status wildlife species within the vicinity of the project sites. Although special-status wildlife species in Table C-2 may have potential to occur in the vicinity of the project sites, it does not necessarily indicate that species are present on either site. Table 4.6-2 evaluates those species which have potential to occur on the project sites.

particularly from cattle grazing, shallowness of the depression and restricted capacity to retain appropriate water depth for a sufficient period of time. In addition, there are no suitable breeding ponds for either species in the immediate vicinity of either project site. However, the project sites are within the range of both species and both sites support grassland or ruderal grassland communities that could potentially provide subterranean aestivation habitat. This determination is based on the possible occurrence of breeding ponds within one to two miles of each site, which is generally regarded as the maximum distance that either species is likely to travel between breeding ponds and upland aestivation sites. Although surveys were not conducted on neighboring lands outside the immediate vicinity of the project sites, a brief review of aerial photos indicates that there are stock ponds within one to two miles of both project sites. However, both species are considered very unlikely to occur on either site due to the following conditions:

- Both project sites are highly disturbed. Vegetation and soil conditions on the Tesla Portal site are damaged due to extensive overgrazing. The project footprint at the Thomas Shaft site has been graded and is significantly disturbed.
- There is no suitable aquatic breeding habitat on or in the immediate vicinity of either project site. While there is a large stock pond within approximately 0.25 miles of the Thomas Shaft site and two small stock ponds within approximately one mile of the Tesla site, the stock ponds are not considered suitable breeding habitat because they have been reported in the past to support fish and bullfrogs that are known to prey on frog larvae (Tetra Tech, 2004c, 2004d).
- The footprints of both sites are very small relative to the surrounding landscape and the availability of potential grassland aestivation habitat.
- CNDDB records indicate that the closest California red-legged frog occurrence is approximately 3.5 miles northwest from the Tesla Portal site and 5.5 miles from the Thomas Shaft.
- CNDDB records indicate that the closest California tiger salamander occurrence is approximately 3 miles northwest from the Tesla Portal site and 5 miles from the Thomas Shaft site.

Therefore, the potential for use of either site by aestivating California red-legged frogs or California tiger salamanders is considered very low.

San Joaquin Whipsnake and California Horned Lizard. Suitable breeding and foraging habitat for the San Joaquin whipsnake and California horned lizard is considered present at both project sites. However, the potential for occurrence of these species is considered unlikely due to the following conditions:

- Both project sites are highly disturbed. Vegetation and soil conditions on the Tesla Portal site are damaged due to extensive overgrazing. The project footprint at the Thomas Shaft site has been graded and is significantly disturbed.

- The footprints of both project sites are very small relative to the surrounding landscape and the availability of potential grassland habitat.

- There are no records of either species occurring on or in the vicinity of either project site (the nearest occupied habitat for either species is Corral Hollow, which is 1.5 miles away), and none were observed during surveys of the project sites.

Therefore, the potential of occurrence of the San Joaquin whipsnake and California horned lizard at the project sites is considered low.

San Joaquin Kit Fox. The San Joaquin kit fox is considered to have potential to occur on both project sites. While this species is very rare in this area in its northern range,[4] both project sites occur within its known range. CNDDB records indicate that the closest San Joaquin kit fox occurrence is approximately 0.25 mile north- northwest of the Tesla Portal site and 1.25 miles from the Thomas Shaft site. Grassland habitats at both sites have evidence of ground squirrel activity (which San Joaquin kit fox often use as dens) and are, therefore, considered potentially suitable for this species. Although the project sites are within the designated range of the species and habitat conditions are suitable, occurrence potential is considered low because of the extreme rarity of the species in the region, the degraded habitat conditions on both sites, and the proximity to human disturbances from the existing facilities at both sites.

San Joaquin Pocket Mouse. CNDDB records indicate that the closest San Joaquin pocket mouse occurrence is more than 3 miles from the Tesla Portal site and over 1 mile from the Thomas Shaft site. Both project sites are within the known range of the San Joaquin pocket mouse and both sites contain suitable, but degraded, breeding and/or foraging annual grassland habitat. Thus, while there is potential for the San Joaquin pocket mouse to be present onsite, because of the degraded habitat conditions and the availability of higher value habitat outside the project areas, the potential for occurrence is considered low.

Pallid Bat, Townsend Bat and Mastiff Bat. The project sites do not contain potential breeding or roosting habitat for any special status bat species. Furthermore, the closest special-status bat occurrence is more than 10 miles from both the Tesla Portal site and the Thomas Shaft site Nevertheless, each species could potentially forage in the grasslands at the Tesla Portal and Thomas Shaft sites.

Burrowing Owl. Although the presence or absence of burrowing owls has not been confirmed in the vicinity of the Tesla Portal site, the site supports suitable nesting and foraging habitat for this species. However, no burrowing owls or active burrows have been detected during any of the project surveys. Nonetheless, suitable rodent dens and holes were detected as present at both sites that are suitable to support burrowing owl breeding activity at Tesla Portal. Suitable habitat for this species was also initially considered present at the Thomas Shaft site (Tetra Tech, 2004b),

4 The northern range of the San Joaquin kit fox refers to the area northwest of the City of Tracy.

but with follow-up inspection of the site, it is considered unlikely to support this species because the canyon is too steep and narrow; burrowing owls occur in some coast ranges habitat – such as within the Altamont Pass area, but typically in areas that are more flat and open than the Thomas Shaft site (May & Associates, 2008a).

Swainson's Hawk. The Tesla Portal project site is within the range of the state-listed Swainson's hawk. The project site supports suitable grassland foraging habitat and adjacent eucalyptus trees that could be used for nesting. Therefore, Swainson's hawk may potentially nest and forage adjacent to or on the Tesla Portal site. Swainson's hawk is not likely to occur at the Thomas Shaft site because the species requires generally flat, open landscapes for nesting and foraging. The steep, narrow canyon where the Thomas Shaft site is located is not suitable for Swainson's hawk nesting or foraging. CNDDB records indicate that the closest Swainson's hawk occurrence is approximately 5.5 miles east of the Tesla Portal site and 4 miles from the Thomas Shaft site.

White-tailed Kite. Both project sites are within the range of the white-tailed kite. CNDDB records indicate that the closest white-tailed kite occurrence is more than 10 miles from both the Tesla Portal site and Thomas Shaft site. This species could potentially nest in the pepper or eucalyptus trees at the Tesla Portal site. It has been confirmed that this species forages at the Tesla Portal site (May and Associates, 2008a). In addition, the white-tailed kite may also forage in the grasslands at the Thomas Shaft project site.

Special-Status Raptor Species (Ferruginous Hawk, Golden Eagle, Prairie Falcon and Northern Harrier). While none of these special-status raptors have potential to nest on either project site, each species is known or has potential to forage on both project sites. CNDDB records do not include occurrence information for special-status raptor species, therefore, distances to known occurrences are not reported.

Tricolored Blackbird. Foraging habitat for tricolored blackbirds is present at both project sites, and tricolored blackbirds are known to forage at the Tesla Portal site (May and Associates, 2008a). This species is not known to breed at either site due to the lack of suitable breeding habitat. CNDDB records indicate that the closest tricolored blackbird occurrence is approximately 4.5 miles south-southeast of the Tesla Portal site and approximately 3 miles from the Thomas Shaft site.

California Horned Lark. The presence of California horned lark has not been confirmed at either the Tesla Portal or Thomas Shaft site. However, based on the similarity of habitat onsite to those known to support the species, potential for occurrence is considered high. California horned lark has potential to breed and forage at the Thomas Shaft project site and at the Tesla Portal project site. CNDDB records indicate that the closest California horned lark occurrence is approximately 1 mile east of the Tesla Portal site and 0.5 miles from the Thomas Shaft site.

4.6.2 Regulatory Framework

Special-Status Species and Other Species of Concern

Federal Endangered Species Act

The Federal Endangered Species Act (FESA) (16 USC 1530 et seq.), was created to provide protections for species that are in danger of becoming extinct. Section 9 of the FESA prohibits the "take" (i.e., killing, harassing, or habitat destruction of) federally-listed species, which is regulated by the U.S. Fish & Wildlife Service (USFWS) and the National Marine Fisheries Service. Take of listed species that is incidental to an otherwise lawful activity under Section 10 of the FESA, is allowed if a project proponent completes a Habitat Conservation Plan (HCP) for that species (16 USC 1539). An HCP accompanies a permit application to "take" a certain number of threatened and endangered species or acres of their habitat over a certain period of time, and demonstrates that the permit applicant will compensate for the taking so as to achieve "no net reduction" in the species' chances for survival.

The USFWS also publishes a list of candidate species for listing. Species on this list receive special attention from federal agencies during environmental review, although they are not otherwise protected under FESA. The candidate species are those for which the USFWS has sufficient biological information to support a proposal to list as endangered or threatened. The proposed project contains potential habitat for federally listed endangered or threatened species and, therefore, would be subject to the requirements of the FESA.

The San Joaquin County Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) has been approved by the USFWS and the CDFG and it covers San Joaquin County, including the project sites. As described in more detail below, the adopted SJMSCP provides for third-party project proponents like the SFPUC to obtain coverage under Section 10 of the FESA for any projects within the plan study area that comply with the SJMSCP requirements.

California Endangered Species Act

Under the California Endangered Species Act (CESA), the CDFG has the responsibility for maintaining a list of threatened and endangered species (California Fish and Game Code Section 2070). The CDFG also maintains a list of candidate species, which are species that the CDFG has formally noticed as being under review for addition to either the list of endangered species or the list of threatened species. The CDFG also maintains lists of "species of special concern," which are animal species whose populations have diminished and may be considered for listing if declines continue. An agency reviewing a proposed project under CEQA must determine whether any state-listed endangered or threatened species may be present in the project area and determine whether the project will have a potentially significant impact on such species. Similar to FESA, the CESA prohibits take of a listed species, which is regulated by the CDFG.[5] Actions otherwise prohibited under CESA can be authorized under the state's Natural Community Conservation Planning Act (Fish and Game Code Sections 2800–2840), which includes a process that is

[5] Note that CESA's definition of "take" is somewhat less stringent than the federal definition under FESA.

analogous to a Section 10 HCP. Specifically, if the species is listed by CESA, and a proposed project would result in impacts, an incidental take permit pursuant to Section 2081 of the Fish and Game Code would be necessary. The CDFG will issue an incidental take permit only if:

- The authorized take is incidental to an otherwise lawful activity
- The impacts of the authorized take are minimized and fully mitigated
- The measures required to minimize and fully mitigate the impacts of the authorized take are roughly proportional in extent to the impact of the taking on the species; maintain the project applicant's objectives to the greatest extent possible; are capable of successful implementation; and adequate funding is provided to implement the required minimization and mitigation measures and to monitor compliance with, and the effectiveness of, the measures

The proposed project contains plant and wildlife species that are listed under CESA. Similar to the federal process, the SJMSCP provides incidental take coverage for state-listed species under CESA. As described in more detail below, the SJMSCP would provide authorization for potential impacts from these projects. Regardless, impacts to CESA listed species would be considered a significant impact under CEQA.

California Native Plant Protection Act

The California Native Plant Protection Act (Fish and Game Code Sections 1900–1913) and the Natural Communities Conservation Planning Act provide guidance on the preservation of plant resources; these two acts underlie the language and intent of Section 15380(d) of the CEQA Guidelines. Vascular plants listed as rare or endangered by the CNPS (2001), but which have no designated status or protection under federal or state endangered species legislation, are defined as follows:

- List 1A: Plants presumed extinct
- List 1B: Plants rare, threatened, or endangered in California and elsewhere
- List 2: Plants rare, threatened, or endangered in California, but more numerous elsewhere
- List 3: Plants about which more information is needed – a review list
- List 4: Plants of limited distribution – a watch list

In general, plants appearing on CNPS List 1A, 1B, or 2 are considered to meet the criteria of Section 15380 of the CEQA Guidelines. Additionally, plants listed on CNPS List 1A, 1B, or 2 also meet the definition of Section 1901, Chapter 10 (Native Plant Protection Act) and Sections 2062 and 2067 (CESA) of the California Fish and Game Code. The project sites have been surveyed for the presence of plants that are listed by the CNPS and, therefore, any impact to these special status plants would be considered a significant impact under CEQA.

Other Statutes, Codes and Policies Affording Limited Species Protection

Migratory Bird Treaty Act

The federal Migratory Bird Treaty Act (MBTA) (16 USC, Section 703, et. seq.) prohibits killing, possessing, or trading in migratory birds, except in accordance with regulations prescribed by the Secretary of the Interior. This act encompasses whole birds, parts of birds, and bird nests and eggs. For projects that would not result in the direct mortality of birds, the MBTA is generally interpreted in CEQA analyses as protecting active nests of all species of birds that are included in the "List of Migratory Birds" published in the Federal Register in 1995. The MBTA would apply to this project because both project sites have potential habitat (foraging and /or breeding) for birds listed under the MBTA. Therefore, potential impacts to migratory birds would be considered a significant impact under CEQA.

State MBTA

Similar to the federal MBTA, Section 3503 of the California Fish and Game Code makes it unlawful to take, possess, or needlessly destroy the nest or eggs of any bird, except as otherwise provided by this code or any regulation made pursuant thereto.

Section 3503.5 states that it is "unlawful to take, possess, or destroy any birds in the order Falconiformes or Strigiformes (birds of prey) or to take, possess, or destroy the nest or eggs of any such bird except as otherwise provided by this code or any regulation adopted pursuant thereto." These sections of the California Fish and Game Code would apply to this project because the project sites contain potential nesting habitat for birds and, impacts to a nest or egg would be a significant impact under CEQA.

Federal and State Provisions Applying to Wetlands

For jurisdictional purposes, there are two definitions of a wetland, one adopted by federal agencies and another adopted by the State of California. Both definitions are presented below.

Federal Wetland & Waters of the United States Definition. Wetlands are a subset of "Waters of the United States" and receive protection under Section 404 of the Clean Water Act. The term "Waters of the United States,"[6] as defined in Code of Federal Regulations (33 CFR 328.3[a]; 40 CFR 230.3[s]), includes:

1. All waters which are currently used, were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters which are subject to the ebb and flow of the tide.

[6] Based on the Supreme Court ruling in Solid Waste Agency for Northern Cook County v. USACOE (531 U.S., 159 (2001) concerning the Clean Water Act jurisdiction over isolated waters (January 9, 2001), non-navigable, isolated, intrastate waters are no longer defined as waters of the United States based solely on their use by migratory birds. Jurisdiction of non-navigable, isolated, intrastate waters may be possible if their use, degradation, or destruction could affect other waters of the Unites States, or interstate or foreign commerce. Jurisdiction over such other waters should be analyzed on a case-by-case basis.

2. All interstate waters including interstate wetlands. (Wetlands are defined by the federal government [CFR, Section 328.3(b)] as those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions.)

3. All other waters such as intrastate lakes, rivers, streams (including intermittent streams), mud flats, sand flats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds, the use, degradation, or destruction of which could affect interstate or foreign commerce including any such waters which are or could be used by interstate or foreign travelers for recreational or other purposes; or from which fish or shellfish are or could be taken and sold in interstate or foreign commerce; or which are used or could be used for industrial purposes by industries in interstate commerce.

4. All impoundments of waters otherwise defined as waters of the United States under the definition.

5. Tributaries of waters identified in paragraphs (1) through (4).

6. Territorial seas.

7. Wetlands adjacent to waters (other than waters that are themselves wetlands) identified in paragraphs (1) through (6).

8. Waters of the United States do not include prior converted cropland. Notwithstanding the determination of an area's status as prior converted cropland by any other federal agency, for the purposes of the Clean Water Act, the final authority regarding Clean Water Act jurisdiction remains with the U.S. Environmental Protection Agency.

Wetlands are specifically delineated using the Wetland Delineation Manual USACOE 1987 and, in California, the Supplement for the Arid West Region. However, these wetlands may not be federally jurisdictional if considered isolated from other Waters of the U.S. The Supreme Court's 2001 decision in *Solid Waste Agency of Northern Cook County v. U.S. Army Corps of Engineers* (SWANCC) found that certain "isolated" wetlands and other waters are not within federal jurisdiction under the Clean Water Act.

Regulation of Activities in Wetlands. The regulations and policies of various federal agencies (e.g., USACOE, United States Environmental Protection Agency [U.S. EPA]) mandate that the filling of wetlands be avoided unless it can be demonstrated that no practicable alternatives exist. The USACOE has primary federal responsibility for administering regulations that concern waters and wetlands. In this regard, the USACOE acts under two statutory authorities: the Rivers and Harbors Act (Sections 9 and 10), which governs specified activities in "navigable waters," and the Clean Water Act (Section 404), which governs specified activities in waters of the United States, including wetlands. The USACOE requires that a permit be obtained if a project proposes

to place structures within navigable waters and/or discharges dredged or fill material into waters of the United States below the ordinary high-water mark in nontidal waters. The U.S. EPA has provided the primary criteria for evaluating the biological impacts of USACOE permit actions in wetlands.

California Wetland Definition. California has adopted the Cowardin et al. (1979) classification system to define wetlands. For purposes of this classification, wetlands must have one or more of the following three attributes: (1) at least periodically, the land supports predominantly hydrophytes[7] (at least 50 percent of the aerial vegetative cover); (2) the substrate is predominantly undrained hydric soil; and (3) the substrate is nonsoil and is saturated with water or covered by shallow water at some time during the growing season of each year (Cowardin et al., 1979).

Under normal circumstances, the federal definition of wetlands requires all three wetland identification parameters to be met, whereas the Cowardin definition requires the presence of at least one of these parameters.

- The state's authority to regulate activities in wetlands and waters at the project sites resides primarily with the California Regional Water Quality Control Board (RWQCB), which regulates construction in waters of the United States and waters of the state, including activities in wetlands, under both the Clean Water Act and the State of California's Porter-Cologne Water Quality Control Act. RWQCB must certify that a USACOE permit action meets state water quality objectives (Section 401, Clean Water Act). In response to the SWANCC Supreme Court decision, the SWRCB issued a guidance for the protection of these waters previously within the USACOE's jurisdiction. The RWQCB now takes the lead role in regulating impacts to "isolated" waters that are no longer within federal jurisdiction. These waters are still considered "Waters of the State" pursuant to the Porter-Cologne Water Quality Control Act.

The CDFG is also authorized under the Fish and Game Code, Sections 1600–1607, to develop mitigation measures and enter into a streambed alteration agreement with applicants proposing a project that would obstruct the flow or alter the bed, channel, or bank of a river or stream in which there is a fish or wildlife resource, including intermittent streams and ephemeral streams (i.e., those flowing briefly during and immediately following storm events).

San Joaquin County

The Resources Element of the San Joaquin County General Plan includes provisions on protecting and improving the County's vegetation, fish and wildlife resources and to provide undeveloped open space for nature studies, protection of endangered species and preservation of wildlife habitat. The Resources Element of the General Plan applies to the project since construction of the proposed project could impact special-status plant and/or wildlife species, as well as sensitive biological resources (e.g., riparian and wetland habitat) in San Joaquin County.

[7] The USFWS has developed the following definition for hydrophytic vegetation: "plant life growing in water or on a substrate that is at least periodically deficient in oxygen as a result of excessive water content" (Cowardin et al., 1979).

The following policies in the Resource Element of the San Joaquin General Plan are applicable to the proposed project:

Policy 1. *Resources of significant biological and ecological importance in San Joaquin County shall be protected. These include wetlands; riparian areas; rare and threatened and endangered species and their habitats as well as potentially rare or commercially important species; vernal pools; significant oak groves and heritage trees.*

Policy 2. *No public action shall significantly diminish the wildlife and vegetative resources of the County; cumulatively significant impacts shall be avoided.*

Policy 3. *No net loss of riparian or wetland habitat or values shall be caused by development.*

Policy 6. *Development projects which have the potential to destroy wetlands shall not be permitted, unless*:

(a) no suitable alternative sites exist for the land use, and the land use is considered necessary to the public.

(b) there is no degradation of the habitat of numbers of any rare, threatened, or endangered plant, animal species as a result of the project; and

(c) habitat of superior quantity and superior or comparable quality will be created or restored to compensate for the loss.

Policy 16. *Replacement vegetation generally shall be native vegetation. Landscaping with native trees and shrubs shall be encouraged in urban areas to provide suitable habitat for native wildlife, particularly in proposed open space uses of future development.*

In addition to the policies outlined in the San Joaquin General Plan, the Development Title of San Joaquin County (1995) provides regulations that serve the public health, safety, and general welfare, as well as to implement the policies of the County's General Plan. Division 15, Natural Resources Regulations, mandates that the County develop regulations that would protect trees, riparian habitat, wetlands and waterways. However, regulations have not yet been developed and adopted by San Joaquin County.

Chapter 9-1505, Trees, in the Natural Resources Regulations, protects native oak trees, heritage oak trees, and historical trees in San Joaquin County. Removal of any of these trees requires a discretionary approval from the County, requires the replacement of any impacted trees, and outlines development constraints when construction activities are in proximity of protected trees. Chapter 9-1505 would not be applicable to the proposed project because the project sites do not contain oak trees, heritage oak trees or historical trees.

Chapter 9-1510, Riparian Habitat, protects and preserves the County's riparian habitat. An action that would have the potential to destroy, eliminate, or degrade riparian habitat would require a discretionary approval from the County. The regulation mandates mitigation requirements for the loss of riparian habitat, as well as institutes a natural bank buffer for riparian habitat. Chapter 9-1510 would not be applicable to the proposed project because the project sites do not contain riparian habitat.

Conservation Planning

San Joaquin County Multi-Species Habitat Conservation and Open Space Plan

The San Joaquin County Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) provides a strategy for conserving open space while addressing the need to convert open space to non-open space uses, protecting agricultural resources, preserving property rights and providing for the long-term management of plant, fish and wildlife species, especially special-status species. A Joint Powers Authority/Technical Advisory Committee (JPA/TAC) implements the SJMSCP.

The SJMSCP covers all of San Joaquin County. Permit holders under the SJMSCP include San Joaquin County, the cities of Escalon, Lodi, Manteca, Stockton, Lathrop, Ripon, and Tracy, the San Joaquin Council of Governments (SJCOG), and others. The SJMSCP is designed to provide a regional approach to mitigating development impacts on the 97 listed and non-listed plant, fish, and wildlife species covered by the SJMSCP and compensating for the conversion of open space to non–open space uses. The SJMSCP provides incidental take authorization for covered projects that implement certain approved incidental take mitigation measures (ITMMs) and, if applicable, provides compensation for habitat losses through the collection of fees that are used to preserve habitats elsewhere. Mitigation measures developed for the proposed project are based on the standard SJMSCP ITMMs, although some have been altered given the magnitude or extent of the potential impact and the features of the project site.

The mitigation ratios and fees are determined based on the following four land cover types:

- Multipurpose open space lands
- Agricultural land
- Natural lands
- Vernal pools

Although the SFPUC is not a signatory to the SJMSCP, the project sites are within the SJMSCP study area, and the proposed projects are considered SJMSCP Covered Activities, which means that the SFPUC may obtain incidental take coverage under the SJMSCP for potential impacts to covered species after consultation with the JPA/TAC. The SFPUC has participated in the SJMSCP process on another project in San Joaquin County (the Thomas Shaft Roadway Improvement Project). The proposed project would participate in the SJMSCP as part of its required mitigation for impacts to aquatic habitat, natural lands and to obtain any necessary incidental take coverage for federally- and state- listed species.

4.6.2 Impacts

Significance Criteria

The City and County of San Francisco has not formally adopted significance standards for impacts related to biological resources, but generally considers that implementation of the proposed project would have a significant impact if it were to:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS
- Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by the CDFG or USFWS
- Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act and as protected under the Porter-Cologne Water Quality Control Act (including but not limited to marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means
- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites
- Have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, or substantially reduce the number or restrict the range of an endangered, rare or threatened species
- Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance
- Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan

Areas of No Project Impact

Several of these criteria are not applicable to the proposed project, as there either is no potential for the impact to occur, or the applicable environmental resource does not occur within the study area or the area of potential effect. The project would not conflict with the SJMSCP because the proposed project is considered a "covered activity," which means that the SFPUC may obtain incidental take coverage under the SJMSCP for potential impacts to covered species after consultation with the JPA/TAC. Impacts from the proposed project would be sufficiently small and would not preclude implementation of the SJMSCP, or protection of the covered species. The project would also be consistent with the ITMMs in the SJMSCP. The project sites do not contain oak trees, heritage oak trees or historical trees, and therefore would not conflict with the San Joaquin County regulation protecting such resources, nor would the project conflict with other known local or regional policies or ordinances protecting biological resources. Moreover,

implementation of the proposed project would not interfere with the movement of migratory fish or wildlife species or with an established migratory corridor, as no movement corridors were identified on either project site. Therefore, the proposed project would have no impact with respect to these significance criteria.

The Thomas Shaft project site does not contain wetland or aquatic resources; therefore, the project would not have any effect on such resources.

Approach to Analysis

The biological resources analysis evaluates potential short-term and long-term impacts associated with special status species, as well habitat modification attributed to the construction and/or operation of the proposed Thomas Shaft and Tesla Portal facilities. In general, implementation of the proposed project would not result in significant direct long-term or short-term effects on biological resources of regional and local surface waters, given compliance with existing regulations and established project procedures, and the implementation of mitigation measures outlined in this section.

Construction Impacts

Impact 4.6-1: Impacts on wetlands and aquatic resources (Tesla Portal: PSM; Thomas Shaft: N/A)

The Tesla Portal site does not contain any natural wetlands or other Waters of the United States that are under the jurisdiction of the USACOE pursuant to the Clean Water Act of 1972 (May & Associates, 2008b). In addition, according to the SFPUC coordination with the RWQCB, it is likely that the artificial wetland would not be considered a Water of the State as defined by the Porter-Cologne Water Quality Control Act. Regardless of agency jurisdiction, this EIR treats the artificial wetland as an important biological resource that may be affected due to changes in project operations (refer to Impact 4.6-4 below).

The ephemeral drainage is considered a Water of the State under the Porter Cologne Water Quality Control Act and California Fish and Game Code, Sections 1600–1607.

Installation of the pipeline (e.g., trenching) where it crosses the ephemeral drainage at the Tesla Portal site would temporarily affect less than 0.001 acre of the site's ephemeral drainage. Project construction could result in minor temporary degradation of the ephemeral drainage's bed and bank, as well as affect the down stream portions of the ephemeral drainage by increasing sedimentation and erosion. These impacts would be considered potentially significant. Impacts to the ephemeral drainage would be subject to the RWQCB's jurisdiction and review, and potentially a 1602 *Streambed Alteration Agreement* from CDFG. Mitigation Measures 4.6-1a and 4.6-1b require the payment of a fee to the SJMSCP for the replacement of habitat that would be equal to that of the temporary loss of <0.001 acre of ephemeral drainage, as well as the implementation of best management practices (i.e., fencing, erosion control and re-contouring of

the impact area) that would reduce impacts to the ephemeral drainage to a less than significant level.

Impact 4.6-2: Impacts on sensitive habitats, common habitats, and heritage trees (Tesla Portal: PSM; Thomas Shaft: LS)

Tesla Portal Site

Temporary impacts resulting from construction staging and other construction-related activities at the Tesla Portal project site would result in impacts to 11.716 acres of California annual grasslands, <0.001 acre of ephemeral drainage, and 0.846 acre of ruderal/disturbed habitat. Ruderal/disturbed habitat at the Tesla Portal site does not support important natural resources or functions and, therefore, the project construction impacts would be less than significant with respect to this habitat. Additionally, no heritage trees would be impacted by construction-related activities at the project site.

Temporary impacts to California annual grasslands and aquatic habitat would contribute to the degradation of natural habitat in the region and could result in the potential permanent loss of habitat. Mitigation Measures 4.6-1a, 4.6-1b and 4.6-2 (participation in the SJMSCP, implement Best Management Practices and returning the site to pre-project conditions) would reduce potential temporary construction impacts to less than significant. Ruderal/disturbed habitat at the Tesla Portal site does not support important natural resources or functions and, therefore, the loss would not result in a significant impact.

Thomas Shaft Site

Temporary construction at the Thomas Shaft project site would result in impacts to 0.110 acre of ruderal/disturbed habitat. No trees would be impacted by construction-related activities at the project site. Ruderal/disturbed habitat at the Thomas Shaft site does not support important natural resources or functions and, therefore, the loss during project construction would not result in a significant impact.

Impact 4.6-3: Impacts on special-status species – direct mortality and/or habitat effects (Tesla Portal: PSM; Thomas Shaft: PSM)

No special status plants were observed at either the Tesla Portal or Thomas Shaft sites. One species, the Mt. Diablo cottonweed, was observed along the access road leading to the Thomas Shaft site, but is not located within the project footprint and staging area at this site; therefore, it would not be impacted by the proposed project. Sensitive plant species are considered unlikely to occur because the project sites lack suitable habitats to support them. Therefore, the proposed project would not result in significant impacts to special status plant species.

Implementation of the proposed project could result in significant impacts to special-status wildlife species with potential to occur in the Tesla Portal and Thomas Shaft project sites. Eighteen special status species with potentially suitable habitat could be present at one or both of the project sites, and six of these special-status wildlife species were either reported to occur onsite or were directly observed (as shown on Table 4.6-2). Project construction could result in temporary loss of foraging and/or breeding habitat for some or all of the special status species known to occur, or with potential habitat present at the project sites.

Mitigation Measure 4.6-1a requires the SFPUC to participate in the SJMSCP and implement incidental take mitigation measures (ITMM)s, to mitigate for impacts on special-status species, thus reducing impacts on biological resources to a less than significant level. SFPUC will adopt all applicable ITMMs and mitigation measures for each species described below that have been identified in the SJMSCP and other measures that have been agreed upon by the SFPUC and the JPA/TAC. A discussion of potential impacts on sensitive and regulated wildlife species, as well as proposed mitigation measures follow:

California Red-Legged Frog and California Tiger Salamander. The potential for use of either project site by aestivating California red-legged frogs or California tiger salamanders is considered very low, and the potential for construction activities (e.g., grading, excavation and/or vegetation removal) resulting in a take of either species is considered negligible. Impacts would be less than significant.

San Joaquin Whipsnake and California Horned Lizard. The project sites contain potential breeding and/or foraging habitat for the San Joaquin whipsnake and the California horned lizard. The proposed project's construction related activities would temporarily reduce the amount of suitable breeding and/or foraging habitat onsite and could result (although unlikely) in the take of one or both of the special-status species. Mitigation Measures 4.6-3a and 4.6-3b would reduce potential impacts to a less than significant level. Measures include a worker awareness program, preconstruction surveys and SFPUC's participation in the SJMSCP that would contribute to the acquisition and preservation of land that is used by the San Joaquin whipsnake and the California horned lizard. If the species are discovered on either of the project sites, additional ITMMs will be formulated by the SJMSCP Technical Advisory Committee (TAC) and approved by the Joint Powers Authority (JPA) with concurrence of the regulatory agencies (CDFG and/or USFWS) representatives. Approved ITMMs may consist of preconstruction surveys, avoidance techniques and/or buffer areas that would reduce impacts to a less than significant level

San Joaquin Kit Fox. The San Joaquin kit fox is also considered to have potential, although unlikely, to occur on both project sites. Construction at the project sites would temporarily reduce the amount of potential breeding and/or foraging habitat onsite and may result in the take of this listed species. Implementation of Mitigation Measures 4.6-3a and 4.6-3c would reduce potential impacts to a less-than-significant level. Mitigation Measure 4.6-3c requires the SFPUC's participation in the SJMSCP and contribution to the acquisition and preservation of land that is used by the San Joaquin kit fox. In addition, SFPUC will adopt all applicable ITMMs that have been identified in the SJMSCP, such as conducting pre-construction surveys and monitoring dens.

San Joaquin Pocket Mouse. The project sites contain suitable breeding and/or foraging habitat for the San Joaquin pocket mouse. Although the overall potential for impacts on this species is considered low, construction activities at the project sites would temporarily reduce the amount of suitable habitat for the species onsite, and may result in potential take. Potential impacts would be reduced to a less than significant level with implementation of Mitigation Measures 4.6-3a and 4.6-3d requiring a worker awareness program, preconstruction surveys, and buffer areas. Mitigation would reduce impacts to a less than significant level.

Pallid Bat, Townsend Bat and Mastiff Bat. The project sites contain foraging habitat for the Pallid, Townsend and Mastiff bats. The proposed project's construction activities would result in the temporary reduction of foraging habitat onsite for these special status bat species. However, given the relatively small size of each project and the lack of direct impacts to bat roosting sites, potential impacts would be less than significant.

- *Burrowing Owl*. The Tesla Portal project site supports suitable habitat (breeding and foraging) conditions for burrowing owls. Construction activities at the Tesla Portal site would temporarily reduce the amount of breeding and foraging habitat onsite and may result in take of this special-status species. Implementation of Mitigation Measures 4.6-3a, 4.6-3e, 4.6-3f, and 4.6-3g would reduce potential impacts to a less than significant level. Mitigation Measure 4.6-3a requires the SFPUC to implement a worker awareness program. Mitigation Measures 4.6-3e, 4.6-3f, and 4.6-3g require the SFPUC adopt all applicable ITMMs related to burrowing owls that have been identified in the SJMSCP. The ITMMs include preconstruction surveys and eviction of birds from the project site prior to ground disturbance or construction activities.

Swainson's Hawk. The Tesla Portal project site is within the range of the state-listed Swainson's hawk and supports suitable grassland foraging and breeding habitat (nesting). Construction activities would temporarily reduce the overall amount of breeding and/or foraging habitat onsite, and may result in the take of the species. In addition, construction activities (e.g., noise and/or vibration) may result in the disturbance of nesting pairs, which can lead to abandonment of active nests and possible take of the species, therefore, resulting in a potentially significant impact. Potentially significant impacts associated with nesting Swainson's hawks would be reduced to a less than significant level with implementation of Mitigation Measures 4.6-3a and 4.6-3h, which requires a worker awareness program and preconstruction surveys, as well as any additional SJMSCP ITMMs.

White-Tailed Kite. Both project sites are within the range of the white-tailed kite and contain potential foraging habitat. White-tailed kite are known to forage at the Tesla Portal project site. Breeding habitat for the species is also found on the Tesla Portal site. Construction activities would temporarily reduce potential foraging and breeding habitat and may result in the take of the special status species. Furthermore, construction activities (e.g., noise and/or vibration) could disturb breeding pairs, which could result in nest abandonment and possible take of this species. Potential for impacts on nesting white-tailed kite would be reduced to a less than significant level with implementation of Mitigation Measures 4.6-3a and 4.6-3i, SJMSCP ITMMs requiring a

worker awareness program, and preconstruction surveys during nesting season or whenever white-tailed kites are identified onsite.

California Horned Lark and Northern Harrier. The California horned lark and northern harrier have potential to nest and forage on both project sites. Construction at the sites would temporarily reduce the overall amount of potential nesting and foraging habitat onsite and could result in the take of the special status species. Mitigation Measures 4.6-3a and 4.6-3j, implementation of a worker awareness program, and SJMSCP ITMMs requiring a 500-foot setback from nesting areas during ground-disturbing activities would reduce potential impacts on breeding and foraging California horned lark and northern harrier habitat to a less-than-significant level.

- *Other Special-Status Raptor Species (Golden Eagle, Ferruginous Hawk and Prairie Falcon).* Each special status raptor species is known or has potential to forage on both project sites. The proposed construction activities would temporarily impact potential foraging and breeding habitat of special-status raptor species. The temporary loss of the small amount of habitat (11.716 acres of grassland), from the project would not substantially affect overall habitat availability in the area or affect foraging behavior of these species or use of the surrounding area. Therefore, the temporary loss of a small amount of disturbed grassland habitat is considered negligible. Impacts would be reduced to less than significant with implementation of Mitigation Measures 4.6-3a, 4.6-3i, 4.6-3-j, 4.6-3k and 4.6-3l, requiring a workers awareness program and SJMSCP ITMMs for each species.

- *Tricolored Blackbird.* Foraging habitat for tricolored blackbirds is present at both project sites, and tricolored blackbirds are known to forage at Tesla Portal. Construction activities at the project sites would temporarily reduce the overall amount of tricolored blackbird foraging habitat onsite. However, given that suitable foraging habitat is so widespread in the region surrounding the project sites, impacts would be minimal and localized. Therefore, the temporary loss of foraging habitat for tricolored blackbirds is considered minor. Impacts would be less than significant.

Operational Impacts

Impact 4.6-4: Impacts on wetlands and aquatic resources (Tesla Portal: PSM; Thomas Shaft: N/A)

Implementation of the proposed project at Tesla Portal would discontinue the discharge of water from the analyzer equipment to the artificial wetland. This would result in the permanent loss of 0.308 acre of artificial wetland. The artificial wetland has little natural water source other than natural runoff and discharges from the Tesla Portal facility; therefore, the long-term effect of this action would be loss of most or all of the artificial wetland. Although the artificial wetland does not appear to have jurisdictional status under either the USACOE or the RWQCB regulations, the loss of the artificial wetland is considered potentially significant pursuant to CEQA because of its habitat value. Implementation of the project would result in the loss of wetland functions and

values (i.e., the only year-round source of water in the project area and surrounding valley bottom), and would substantially degrade or diminish habitat values for dependent plant and wildlife species.

Mitigation Measure 4.6-1a requires participation in the SJMSCP for the replacement of habitat that would be equal to that of the permanent loss of 0.308 acre of artificial wetland; therefore, the impact would be reduced to a less than significant level.

Impact 4.6-5: Impacts on sensitive and common habitats (Tesla Portal: LS; Thomas Shaft: LS)

Implementation of the proposed project at the Tesla Portal site would result in the permanent loss of approximately 3.2 acres of California annual grassland and 0.308 acre of artificial wetland. (Impacts associated with the loss of 0.308 acre of artificial wetland at the Tesla Portal site are addressed above, under Impact 4.6-4.) Implementation of the proposed project at the Thomas Shaft project site would result in the permanent loss of 0.008-acre ruderal/disturbed habitat.

Loss of California annual grasslands would contribute incrementally to the statewide loss of this type of habitat. However, given the abundance of similar grassland habitats in the immediate area and adjacent to the project sites and the relatively small amount of habitat loss, impacts associated with this project would be less than significant, as the loss of California annual grassland at the project sites is not expected to substantially reduce this resource overall. The proposed project would not substantially degrade the function of this habitat type in the local context of the project sites, and would not result in severe habitat fragmentation. Ruderal/disturbed habitat at the Thomas Shaft project site does not support important natural resources or functions and, therefore, the loss would not result in a significant impact.

Impact 4.6-6: Impacts on special-status species – direct mortality and/or habitat effects (Tesla Portal: LS; Thomas Shaft: LS)

Implementation and operation of the proposed project would not result in the direct mortality of any special status wildlife or plant species. However, implementation and operation of the proposed project would result in the permanent reduction of special-status wildlife foraging and/or breeding habitat. In total, the proposed project (Tesla Portal and Thomas Shaft) would convert 3.2 acres of California annual grasslands and 0.008 acre of ruderal habitat into a developed area. The project would result in the permanent loss of breeding and/or foraging habitat to all of the 18 special-status wildlife species with potential to be present on either project site (refer to Table 4.6-2). However, given the abundance of higher quality special-status species habitat in the proximity of the project sites, as well as the relatively small size of the proposed project footprints, impacts would be less than significant.

4.7 Cultural Resources

This section is based on two technical reports prepared by Garcia and Associates (GANDA) in March 2008: *Archaeological and Cultural Resources for the Tesla Portal Disinfection Station and Thomas Shaft Site for the San Joaquin Regional Water Quality Improvement Project* (archaeological/architectural resources technical report) and *Paleontological Resources Technical Report and Survey at the Tesla Portal Disinfection Station and Thomas Shaft Facility for the San Joaquin Regional Water Quality Improvement Project* (paleontological resources technical report).

4.7.1 Setting

Paleontological Setting

Regional Geology

The regional geology of the Tesla Portal and Thomas Shaft sites is described in Section 4.4, Geology, Soils, and Seismicity. Both project sites are located on geologic formations that are likely to contain fossils and, therefore, are considered sensitive for paleontological resources. Pleistocene alluvium and Miocene marine sandstones of the San Pablo Group have high paleontological sensitivity. Franciscan Complex sandstones are also known to contain fossil resources, while Pliocene fanglomerates have an undetermined paleontological sensitivity. Paleontological resources within this area consist of the fossilized remains of plants and animals, including vertebrates (animals with backbones) and invertebrates (e.g., starfish, clams, ammonites, and coral marine).

Paleontological Sensitivity of the Project Areas

Fossil localities (locations where paleontological resources have been documented) are near both the Tesla Portal and Thomas Shaft sites. Five paleontological sites exist within a one-mile radius of the Thomas Shaft site and two paleontological sites exist within a one-mile radius of the Tesla Portal site, one of which exists within the Tesla Portal project area. Six localities are recorded within 5 miles of the Tesla Portal site and 15 localities are recorded within 5 miles of the Thomas Shaft site (BNHM, 2007). Eight vertebrate fossils have been discovered at the six localities within 5 miles of the Tesla Portal site and 226 vertebrate fossils have been encountered at the 15 localities within 5 miles of the Thomas Shaft site. One of the fossil localities within 5 miles of the Tesla Portal site was recorded during the original construction of the Hetch Hetchy Aqueduct, and is known by that name (BNHM, 2007). This fossil locality yielded an ancient camel skull of the genus *Camelops*. Another fossil locality less than 5 miles north of the Tesla Portal site yielded a very important Type specimen of a Jurassic Ichthyosaur (BNHM, 2007).[1] Fossils encountered within 5 miles of the Thomas Shaft site consist of a number of terrestrial vertebrate taxa from many different groups of mammals and reptiles, including the early horse genera *Nannipus* and *Hipparion* (Stirton, 1939).

[1] A Type specimen is used as a standard to determine if similar specimens belong to the same species.

Archaeological/Prehistoric Period Setting

Archaeological resources may be prehistoric, historic, or both. This discussion of prehistoric archaeological chronology addresses cultural patterns in the project area vicinity from the time when the first recorded artifacts were deposited to the time of European contact. Historic archaeological resources, starting with the Contact Period, are discussed below under "Historical Period Setting."

Chronology and Prehistory of the Region

In attempts to develop a chronology for the San Joaquin Valley, archaeologists have been confronted with numerous challenges for the past 100 years. Archaeologists have faced difficulties in documenting and analyzing the archaeological record due to the level of destruction of surface archaeological sites as a result of agricultural practices, levee building, erosion, and extensive looting.

In the early 1970s, Fredrickson (1973) proposed three basic periods for the Central Valley region: the Paleo-Indian Period, the Lower, Middle and Upper Archaic periods, and the Emergent Period. Rosenthal et al. (2007) have refined these time periods based on newly calibrated radiocarbon dates, given below. The following is a brief discussion of the basic periods of the Central Valley region:

- Paleo-Indian. The Paleo-Indian Period (11,550 to 8550 cal B.C.) has a relatively faint archaeological footprint. The oldest site is the southern San Joaquin Valley at the Witt site of Tulare Lake. Human bone tested from this site yielded dates of 11,379 to 15,802 radiocarbon years before present. Archaeological material from this time period has either been eroded away or buried by alluvial deposits. No sites of this antiquity are known to exist within the project vicinity (Rosenthal et al., 2007).

- Lower Archaic. The Lower Archaic Period (8550 to 5550 cal B.C.) economy emphasized mobile foraging. Artifacts found at sites include handstones, milling slabs, and various cobble tools that indicate a reliance on plant resources. Relationships between foothill and valley floor archaeology have not been explored for this early period, as there is a scarcity of archaeological evidence regarding valley archaeology from the Lower Archaic and Early Middle Archaic time periods.

- Middle Archaic. More distinct cultural adaptations for the valley floor and foothills are visible in sites dating to the Middle Archaic Period (5550 to 550 cal B.C.). Artifact assemblages for the foothill tradition are composed of flaked stone dart points and cobble tools similar to those of the Lower Archaic. Tabular pendants, incised slate, and perforated stone plummets are rare but have wide distribution. Middle Archaic sites are also characterized by rock-filled hearths and ovens, and "cairn capped" graves. The beginnings of other technologies—such as cordage, twined basketry, basketry awls, simple pottery, and other baked clay objects, stone plummets, bird bone tubes, and shell beads—appear in the Middle Archaic.

- Upper Archaic. During the Upper Archaic Period (550 cal B.C. to cal A.D. 1100), the technologies that existed in the Middle Archaic became highly specialized. This is evidenced by new types of tools, as well as by widely traded goods like saucer- and saddle-shaped *Olivella* beads, *Haliotis* ornaments, obsidian biface "roughouts," and ceremonial blades. The Native population focused on economies that included seasonally available resources that could be harvested and processed in large quantities, such as acorns.

- Emergent. The Late or Emergent Period (further divided into Lower and Upper), ranges from as early as cal A.D. 1100 to the time of European settlement, or the late 1700s. Intensive fishing, hunting, and harvesting of acorns and small hard seeds typify this period. A general increase in population and settlements, a more regularized exchange system, and an increase in evidence of ceremonialism characterize the period. Distinctive artifacts in the Central Valley during this period include small notched points that are indicative of the introduction and spread of bow-and-arrow usage, bone awls used in basketry, clay effigies, elaborately incised bone whistles, flanged soapstone stone pipes, and occasional pottery.

Ethnography and Contact Period – Native American Populations

At the time of European contact, Native American groups who spoke the Yokuts and Ohlone languages inhabited eastern Livermore Valley and the western San Joaquin region. The area around the Tesla Portal site was likely occupied by either the Luecha (an Ohlone subgroup) or the Cholvons (a Yokuts subgroup, also referred to as the Chulamni), while the area that now surrounds the Thomas Shaft site was home to the Luecha. The Luecha spoke both Ohlone and Yokuts language variants (Milliken, 1995, 2002).

The combined territory of the Ohlone-speaking people, also known as the Costanoans, extended along the coast from the current day locations of the Golden Gate Bridge in the north to just beyond Carmel in the south, and as much as 60 miles inland. The Ohlone are a linguistically defined group speaking eight different but related languages. The Ohlone were politically organized by tribelet, which consisted of one or more villages and camps within a territory generally designated by geographic features. Tribelet population ranged from about 50 to about 500 persons (Levy, 1978:485). The Ohlone were hunter-gatherers and relied on acorns and seafood and certain terrestrial plants and animals as staple foods. They also exploited a wide range of other foods, including various seeds (the growth of which was promoted by controlled burning), buckeye, berries, roots, land and sea mammals, waterfowl, reptiles, and insects.

The combined territory of the Yokuts-speaking people comprised approximately 250 miles extending down the San Joaquin River to the foot of the Tehachapis and east from the Fresno River to the adjacent foothills of the Sierra Nevada. The Yokuts are commonly categorized into three cultural-geographical types: the Southern Yokuts, Northern Yokuts, and Foothill Yokuts. Northern Yokuts were politically organized by tribelet, each having a designated territory. A tribelet comprised one or more villages and camps within a territory generally designated by geographic features. Tribelets commonly had 200-250 members. The Northern Yokuts were hunter-gatherers and relied on acorns and salmon as staples. They exploited a range of aquatic

birds, including geese and ducks, due to their close proximity to rivers and streams (Wallace, 1978).

Historical Period Setting

In 1542, Juan Sebastian Cabrillo was the first of the exploring Europeans to sail along the California coast. During the next 125 years, the Native Americans had sporadic contact with European explorers. The Portolá expedition left San Diego on July 14, 1769, becoming the first Europeans to explore by land what is now California (Browning, 1992). The goal of this expedition was to explore the new territory and to find worthy locations for establishing Franciscan missions; along the way they rediscovered the Bay of Monterey, described by sailors a hundred years earlier. Several accounts of this expedition exist including those of Fray Juan Crespi (Bolton, 1971), Miguel Costansó (Browning, 1992), and Pedro Fages (Priestley, 1937). Mission Pass, northeast of Mission San Jose, was the starting point of an old Spanish trail, the "Camino del las Buenos Ayres" which later became El Camino Viejo. The expedition of Juan Bautista de Anza and Fray Pedro Font in 1776 used this route, camping in "El Arroyo de los Buenos Aires" near the location of the present-day Tesla Portal site.

As the Spanish began to establish missions, the Yokuts were relocated to Mission San Jose, Mission San Francisco, and Mission San Juan Bautista, while populations of Ohlone were brought into Mission Santa Clara and Mission San Jose. These missions embarked on a campaign to convert the local Native Americans to Catholicism and a European style of farming and labor. Native population numbers were reduced at least eighty percent during this period due to the introduction of European diseases and the dramatic change in their lifestyle, both of which contributed to the destabilization of their remaining social structures. It is likely that by the time of secularization of the Missions circa 1830, there were no functioning tribal groups left within the project areas.

Following secularization of the Missions, representatives of the Mexican government distributed very large land grants to various individuals, who developed cattle ranches. The lands in the San Joaquin Region were divided into the Rancheria del Rio Estanislao, Rancho El Pescadero, Rancho del Puerto, Rancho Orestimba, and Thompson's Rancho. These huge ranchos were later sold and resold in increasingly smaller parcels and later were turned to farming uses. The project sites, however, were not located on or near any land grants. While the Thomas Shaft area has an extensive history, the Tesla Portal site remained comparatively undeveloped until the Coast Range Tunnel excavations relating to the Hetch Hetchy aqueduct began in 1927. In 1846, the first Americans arrived at Corral Hollow, near the present-day location of the Thomas Shaft site. They were a group of emigrants who had separated themselves from the ill-fated Donner-Reed party. Corral Hollow was so named for a horse corral that the leader of this group, Captain Charles Imus, had built in 1847 as part of his plan to capture wild horses. In 1850, a tavern called the Zink House opened at Corral Hollow, providing food and drinks to the forty-niners. The famous hunter Grizzly Adams arrived in Corral Hollow to hunt animals, especially bears, in 1854.

The first coal mine in California began operation in 1856 at the Corral Hollow coal fields near the Tesla location. The Tesla Coal Mine opened in 1897. Corral Hollow coal was shipped to Stockton

for local industry, and local availability influenced the Central Pacific Railroad to convert its engines from wood to coal. However, the advent of oil burning locomotives and industrial machinery depressed the price of coal. After a fire destroyed the coal bunkers and briquette factory in Stockton, the mines closed in 1905. The quartz-rich sands found in the area also had industrial value. These were shipped to Stockton via a railroad line built by the Alameda and San Joaquin Railroad Company, which became the Western Pacific in 1903, to what, at the time, was the only operating glass manufacturer on the west coast. The clay beds in Corral Hollow fostered the birth and growth of the town of Carnegie, on the LLNL Site 300 property across from Corral Hollow Road from the Thomas Shaft roadway entrance. The Carnegie Brick and Pottery Company produced brick and clay sewer pipe from 1903 to 1909, and the company town of Carnegie was built to supply and shelter workers and their families. A catastrophic flood in 1911 brought about the end to most of the activity, other than sheep herding.

While the Thomas Shaft area has some evidence of historic activity, the Tesla Portal site was rather undeveloped until the Coast Range Tunnel excavations relating to the Hetch Hetchy aqueduct began.

Hetch Hetchy Water System

The Hetch Hetchy System is part of the larger San Francisco Water System, which is comprised of the City and County of San Francisco distribution system, the Peninsula system, and the Alameda Creek system. The San Francisco Water System dates back to the Gold Rush of the mid-1800s. During this time period, the population of San Francisco boomed with an influx of fortune seekers. However, because the city is located on a semi-arid peninsula with very little access to fresh water, the existing water supply proved to be inadequate. At that time, water was imported in barrels, and sold at exorbitant prices to San Franciscans. In 1856, the city established the San Francisco Water Works by an official city order. Several other companies competed with the San Francisco Water Works, which ultimately failed. One competitor, the privately owned Spring Valley Water Company, soon came to dominate the city's water distribution with several sources of water supply coming into the city from various dams and reservoirs (Hundley, 2005).

The City of San Francisco undertook the Hetch Hetchy water system as a major part of the movement to wrest control of the water supply from the Spring Valley Water Company. The effort began in 1890, when the Tuolumne River was surveyed as a potential water source for San Francisco and the Hetch Hetchy Valley as a potential reservoir site. Beginning in 1903, San Francisco sought permission from successive federal secretaries of the interior to build a dam in the Hetch Hetchy Valley and to use other federal lands in Yosemite National Park and Stanislaus National Forest to deliver the water to the Bay Area. After a series of denials, Secretary of the Interior James R. Garfield finally granted the request in 1908. However, following this grant of right of way, the presidential administration changed twice and successive roadblocks to the city's procurement of Tuolumne River water ensued, culminating with the recommendation of Secretary of the Interior Franklin Lane that the City of San Francisco seek congressional approval for the Hetch Hetchy permit (Hundley, 2005).

The renowned hydraulic engineer, John R. Freeman, was hired by the city while it was negotiating with the federal government for access to Hetch Hetchy Valley water. Freeman prepared a report that outlined the city's need for this water. The report was instrumental in pushing the project through the approval process. Freeman's report called for the delivery of 160 million gallons per day (mgd) from Hetch Hetchy to San Francisco, with the prospect of increasing that amount to 400 mgd, an amount sufficient to serve the entire Bay Area. Freeman promoted the "urban destiny" of the Bay Area and compared the development of San Francisco's Hetch Hetchy system to the water systems that supported the industrial and population of other major metropolitan areas (URS-ATS Joint Venture, 2008).

- The Sierra Club, along with San Joaquin Valley farmers and the Spring Valley Water Company, contested the damming of the Tuolumne River. Opposition to construction of the Hetch Hetchy project came from a variety of interests. Understandably, the Spring Valley Water Company opposed this project, which effectively ended its role as the utility company supplying San Francisco with its municipal and domestic water (SFPUC, 1949). The Hetch Hetchy project was designed to transmit electrical power to San Francisco from a power plant at Moccasin. A politically charged conflict over this electric power and associated revenue pitted public power advocates against the privately financed electric power industry. Opposition came from electrical power generating companies like PG&E and Great Western Power Company (GWP), two utilities that served San Francisco and the Bay Area at the time. These private power companies opposed the competing generation and sale of electricity by public agencies, which was a provision of the Raker Act. CCSF planned to acquire PG&E and GWP's distribution systems within its service area, but between 1927 and 1941 the public consistently rejected bond issues required to fund their acquisition; allegedly, this opposition to the bond measures was largely funded by PG&E (Hundley, 1992; Sayles, 1985). The CCSF's agreements to have PG&E (which had acquired GWP in the 1930s) wheel its power through the company's existing transmission and distribution systems for delivery to San Francisco agencies, and its purchase of city power for resale, caused a longstanding controversy between the federal government, public power advocates, and the CCSF. An eight-year campaign was waged to thwart the project. However, the opponents were ultimately defeated in 1913 with congressional approval of the Raker Act. The Raker Act provided the City of San Francisco a congressional grant of right-of-way, construction, and use privileges in Hetch Hetchy Valley, which ultimately allowed the Tuolumne River to be dammed and the valley flooded. After passage of the Raker Act, the gigantic Hetch Hetchy undertaking began in earnest. During construction of the Hetch Hetchy system, the city finally completed the long process of acquiring Spring Valley Water Company (Hundley, 2005).

Michael O'Shaughnessy, San Francisco's city engineer from 1912 to 1934, is perhaps the most prominent name associated with the development of the Hetch Hetchy water and power system. O'Shaughnessy was the chief engineer of the Hetch Hetchy project and realized the completion of the San Francisco Water System and the methods for obtaining water from the Sierra Nevada. O'Shaughnessy was responsible for devising the design and function of the water system. O'Shaughnessy also had many of the state's best engineers in his work force (SFPUC, 2005).

The Hetch Hetchy system was a huge engineering accomplishment that overcame many challenges and involved not only building a 167-mile-long aqueduct, but also involved constructing multiple dams, reservoirs, conduits and valvehouses to transport water from high in the mountains down to the coastal city of San Francisco near sea level. There were also powerhouses and other features related to a limited hydroelectric power delivery system. Facilities within the Hetch Hetchy water transmission system were engineered and located to maintain a gravitational flow of water from Hetch Hetchy Reservoir to the San Francisco Bay Area. The entire project was completed in 1938 (SFPUC, 2005).

The construction of the Coast Range Tunnel began in 1927 and was completed in 1934. It is the final leg of the journey for Sierra Nevada waters before they reach the San Francisco Bay Area extending between the Tesla Portal and the Alameda East Portal. SJPL No. 1 was constructed in 1932 as part of the original plan for the San Francisco regional water system. SJPL No. 2 was constructed between 1948 and 1953. The two pipelines were always considered part of the original system plan. In conjunction with the construction of SJPL No. 2, the Southwest Valve House was constructed in 1950 and is located within the Tesla Portal facility.

The Tesla Portal Hypochlorite Station Facility, constructed in 1936-1937, is the primary disinfection system for all waters emanating from the Hetch Hetchy Aqueduct. The original components of the Tesla Portal Hypochlorite Station included the Coast Range Tunnel, the Tesla Portal Structure, and four buildings constructed in the Craftsman style, including the Caretaker's Cottage, the Caretaker's Garage, the Chlorinator Building, and the Pump House.

The original components of the Thomas Shaft site included a tunnel and access shaft, constructed when the Hetch Hetchy Aqueduct was first installed.

Paleontological Resources

No paleontological resources were discovered at either the Tesla Portal site or the Thomas Shaft site during the site reconnaissance (GANDA, 2008b). However, the paleontologically sensitive geologic units, consisting of late Pleistocene alluvium, Miocene San Pablo Group sandstones, and late Mesozoic Franciscan Complex sediments, were identified in or adjacent to both sites. As noted earlier, numerous fossil resources have been discovered within 5 miles of each site.

Prehistoric and Historic Archaeological Resources

No prehistoric or historic archaeological resources were identified at either the Tesla Portal site or Thomas Shaft site during field surveys (GANDA, 2008a). Furthermore, there are no previously recorded prehistoric resources at either site. A cultural resources investigation in 1981 at the Lawrence Livermore National Laboratory (LLNL) Site 300, the southern boundary of which is approximately 1.5 miles north of the Thomas Shaft site, resulted in the identification of 24 cultural resources, including prehistoric rock shelters with associated midden, bedrock mortars, chert lithic scatters, a portion of the Carnegie town site (State Historic Landmark #740), and other isolated historic materials.

Historic Architectural Resources

The Tesla Portal and Thomas Shaft project sites contain potentially significant historic architectural resources including the San Joaquin Pipelines (SJPLs) Nos. 1, 2, and 3, the ten structures on the Tesla Portal site, and the Thomas Shaft facility. These resources, as well as details regarding their eligibility as a historical resource, are presented below. The discussions about eligibility and significance as historical resources are based on the National Register of Historic Places (NRHP) and California Register of Historical Resources (CRHR) criteria, described in Section 4.7.2.

San Joaquin Pipelines No. 1 and No. 2

The SJPLs No. 1 and No. 2 are part of the SFPUC's SJPL System that conveys water across the San Joaquin Valley. SJPLs No. 1 and No. 2 run east-west, connecting the Foothill Tunnel at the Oakdale Portal to the east with the Coast Range Tunnel at the Tesla Portal to the west. The SJPLs are located underground or aboveground and supported on concrete piers.

SJPL No. 1 was constructed in 1932 as part of the original plan for the San Francisco regional water system. A portion of the SJPL No. 1 falls within the Tesla Portal site.

SJPL No. 2 was constructed between 1948 and 1953. Although SJPL No. 2 was constructed over two decades later in 1953, it was deemed a necessary addition to the water system as soon as SJPL No. 1 was completed in 1932, and the two pipelines were always considered part of the original system plan. Similar to SJPL No. 1, a portion of SJPL No. 2 falls within the Tesla Portal site.

Significance and Integrity: SJPLs No. 1 and No. 2 were an integral part of the San Francisco water system design and appear to be significant under NRHP Criterion A and CRHR Criterion 1 at the local level due to their association with first municipally-owned water system for the City of San Francisco. The new system provided a vastly more reliable and purer water supply transmitted from a distant mountain source. In addition, SJPLs No. 1 and No. 2 are historically significant, because they helped resolved the long standing water shortage issue in the Bay Area, facilitated the San Francisco's break from private water companies and was designed to meet demand as far into the future as could be envisioned at the time.

SJPL No. 1 appears to be eligible for listing at the local level under NRHP Criterion C and CRHR Criterion 3 for the innovative engineering techniques used by the Youdall Company during its construction (URS-ATS Joint Venture, 2008). SJPL No. 2 does not appear to be eligible under this criterion because it does not represent a significant engineering evolution or a design innovation.

SJPLs No. 1 and No. 2 appear to retain good integrity including materials, workmanship and design. Routine maintenance of SJPLs No. 1 and No. 2 would not be considered to be significant enough to alter their integrity, have not been moved, and have retained their association with the historic water system. Therefore, SJPLs No. 1 and No. 2 appear eligible for the NRHP and CRHR (URS-ATS Joint Venture, 2008).

San Joaquin Pipeline No. 3

SJPL No. 3, the largest of the three pipelines, is located parallel to SJPLs No. 1 and No. 2. SJPL No. 3 was built in 1968 as an improvement to the existing water system and to provide additional capacity to the SJPL System.

Significance and Integrity: SJPL No. 3 does not convey the historic significance of the San Francisco water system in the same manner as SJPLs No.1 and No. 2. Additionally, SJPL No. 3 does not have an association with the initial development of the San Francisco water system, or the historically significant Michael O'Shaughnessy or Joseph Freeman. Furthermore, SJPL No. 3 is less than 45 years old and, therefore, does not appear to possess the exceptional importance required to meet NRHP Criteria Consideration G for recently constructed resources. Therefore, SJPL No.3 does not appear eligible for the NRHP or the CRHR (URS-ATS Joint Venture, 2008).

Tesla Portal Facility

The Tesla Portal Facility is comprised of 11 structures: the Tesla Portal Manifold Structure, the Caretaker's Cottage, the Caretaker's Garage, the Chlorinator Building, the Pump House/Equipment, Northwest Valve House #1, Southwest Valve House #2, an Office/Storage Building, and three water tanks. These structures as well as their potential eligibility as a historic resource are presented below (see Section 4.7.2, Regulatory Framework, for an explanation of CRHR Criteria). The Coast Range Tunnel is located west of the Tesla Portal Manifold Structure and is a separate resource from the Tesla Portal Facility.

Tesla Portal Manifold Structure: The Tesla Portal Manifold Structure is a section of pipe that was originally completed and connected to the Coast Range Tunnel in 1933; it comprises a 10.5-foot diameter steel manifold where three pipelines join and enter the Coast Range Tunnel. From a historic resources perspective, the Tesla Portal Structure is defined as that portion of the Coast Range Tunnel and ancillary pipe and fittings that are visible above ground, downstream of the SJPLs. It channels water from the SJPLs into the Coast Range Tunnel. The manifold appears to be of more recent construction, and was probably replaced in 1968 during the construction of SJPL No. 3. A steel overflow/surge shaft rises approximately 60 feet from the hillside adjacent to the manifold. This shaft was built in successive steps with each pipeline between 1932 and 1967.

The Caretaker's Cottage: The Caretaker’s Cottage (constructed in 1936) is a one-story, wood-frame California Craftsman style residence with a concrete foundation, featuring concrete stucco-clad walls and a double-gabled composition shingle clad roof. The architectural details of the Caretaker’s House echo those found on the equipment building and chlorination facility building, the composition shingled, double-gabled roof features overhanging eaves and decorative knee-brace roof brackets on the gable ends. The gable end peaks feature basket-weave lattice wood vents above the plaster walls. The Caretaker’s House underwent renovations circa 1963. All windows were replaced with aluminum one-over-one, double-hung windows or aluminum two-light slider windows, and iron security grilles have been placed in front of all of the windows and doors. Many of the windows have been boarded up with plywood coverings. The original wood and glass paneled doors have been removed and replaced with modern doors, security grilles and plywood coverings. A projecting gable door hood was installed over the entrance door on the north façade. There are two shed additions on the rear south elevation.

The Caretaker's Garage: The Caretaker’s Garage (constructed in 1936) is a one-story, wood-frame, Craftsman style garage with a concrete foundation, featuring concrete stucco-clad walls and composition shingle covered gable roof. The gable roof features overhanging eaves with decorative knee-brace brackets at the gable ends. Two sets of double-leaf tongue-and-groove paneled doors that swing in on the north façade are below a centered decorative beveled wooden vent opening. The east, west, and south elevations feature a fixed eight-light wood window, and centered decorative beveled wooden vent openings are located on the north and south elevations. A molded stucco cornice is located under the eave line. A low water table is located at the base of the walls.

The Chlorinator Building: The Chlorinator Building (constructed in 1936) is a one-story wood-frame Craftsman style building with a concrete foundation, featuring concrete stucco-clad walls and an asphalt shingle hip roof with partial gable ends. In 1967, this building received an addition/extension to the east façade concurrent with the construction of SJPL No. 3 (Busby, 2000). The east façade originally featured a 10-foot-deep concrete loading dock with stairs located on the southern end, which was removed. A modern, aluminum roll-up garage door presently fills the northern portion of the east façade. The north and south façades originally featured three large steel frame, multi-pane windows corresponding to the tank storage room and now feature five windows. Lastly, the 18-inch-tall water table has been removed, and two lean-to additions are now located on the west and south façades (SFPUC, 1936).

In addition, three small sheds are located just south of the Chlorinator Building. The western-most building is the smallest and has a rectangular plan with a gable roof. The central building is rectangular in plan and clad in vertical wood board. It has a shed roof that overhangs slightly on its north façade, which also has a solitary door. The eastern most building has a square plan with a flat roof. It is constructed of metal and has a set of metal double doors on its north façade.

The interior of the Chlorinator Building was originally divided into two rooms. A Chlorine Machine Room occupied the western end of the building, and the larger Tank Storage Room occupied the eastern end of the building. A wall with a glazed, paneled door, wooden stairs, and four fixed, multi-pane, wood-sash windows separated the rooms. The building currently houses sodium hypochlorite metering pumps, chlorine residual analyzers, and both the interior and exterior storage tanks. Many exterior pipes and wires are attached to the exterior walls of the building and two storage tanks used to store a liquid form of chlorine are located adjacent to the west elevation.

The Pump House/Equipment Building: The Pump House/Equipment Building (constructed in 1936) is a one-story, wood frame rectangular-shaped Craftsman style building with a concrete foundation, featuring concrete stucco-clad walls and a composition shingle clad gable roof. The gable roof features overhanging eaves and a molded wood cornice with projecting knee-brace brackets under the eaves on the gable ends. The original building, dating from 1936-1937, features a symmetrically placed center paneled door with flanking steel-framed windows with nine-lights (with opaque wire-glass) on the north façade. The original south elevation featured two symmetrically placed steel framed windows with nine-lights of opaque wire-glass. In 1967, this building received two additions/extensions to the east and west, concurrent with the construction of SJPL No. 3 (Busby, 2000). The east end gable elevation features a centered beveled wooden vent opening. A low water table is located at the base of the walls. There are exposed pipes and vents on the exterior walls, and the windows on the additions feature modern security grilles.

Northwest Valve House: Constructed in 1963 in conjunction with SJPL No. 3 (Busby, 2000), the Northeast Valve House is a one-story, one-room, wood frame Spanish Revival style, rectangular-shaped building with a concrete foundation, featuring concrete stucco-clad walls and a clay tile gable roof. The west façade features one steel frame window with eight-lights of wire-glass and a

decorative security grille adjacent to concrete steps leading to a two-panel steel door. The east elevation features a single eight-light steel frame window with a decorative security grille. A 1-2-foot-high molded water table is located at the base of the walls. A molded stucco cornice runs under the roofline. The end bays feature round decorative tile ventilation apertures. A raised stucco panel above the entrance door has no lettering, although other valve houses throughout the water system have been inscribed with lettering that reads "San Francisco Hetch Hetchy Water" and the construction date.

Southwest Valve House: Constructed circa 1950 in conjunction with SJPL No. 2 (Busby, 2000), the Southwest Valve House is a one-story, one-room, wood frame Spanish Revival style, rectangular-shaped building with a concrete foundation, featuring concrete stucco-clad walls and a clay tile gable roof. The symmetrically-placed steel frame windows with eight-lights of wire-glass and decorative security grilles flank a two-panel steel door on the east façade. The west elevation features two symmetrically-placed steel frame windows with eight-lights of wire-glass and decorative security grilles. A 1-to-2-foot-high molded water table is located at the base of the walls. A molded stucco cornice is located under the roofline. The end bays feature round decorative tile ventilation apertures. A raised stucco band above the entrance door with incised lettering reading "San Francisco Hetch Hetchy Water Supply 1950" has been covered over with stucco. Three projecting metal valve structures protrude perpendicularly from the east facade and west elevation.

Office/Storage Building: Constructed between 1963 and 1967, the Office/Storage Building is a one-story, wood frame Craftsman style square-shaped building with a concrete foundation, featuring concrete stucco-clad walls and an asphalt shingle gable roof. The gable roof features overhanging eaves with decorative knee-brace brackets on the gable ends. Replacement aluminum slider windows with two-lights are located in the centered window openings on the east, west and south elevations. A through-the-wall air conditioning unit is on the east elevation.

Water Tanks: There are three 20,000-gallon water storage tanks located on a hill southwest of the Surge Shaft above the Tesla Portal facility. Tank No. 1 and Tank No. 2 were constructed in 1936. Tank No. 3 was constructed in 1950. All three water tanks are painted with aluminum paint, and the site is surrounded by a locked chain-linked fence.

Significance and Integrity: Historical research and evaluation of the Tesla Portal site, as a whole, resulted in the recommendation that the facility does not appear to be eligible for the NRHP and CRHR due to its lack of significant engineering structures, and its lack of integrity and/or the lack of significance of individual buildings and structures within the site. Had the Tesla Portal facility retained sufficient integrity to its inferred period of significance (1933-1953), it would have been eligible for the CRHR.

One individual resource within the complex, the Southwest Valve House, appears to meet NRHP Criterion A and CRHR Criterion 1, with a period of significance of 1950 to 1953 and given its association with the development of the San Francisco water system (URS-ATS Joint Venture, 2008). This period of significance corresponds to the period of expansion and improvement of the

SJPL System, concluding with the completion of SJPL No. 2 in 1953. The Southwest Valve House retains a high level of integrity, given that it retains its original plan, massing and cladding. In addition, the Southwest Valve House retains its integrity of design, materials, workmanship and location. Although structures have been constructed and/or modified in proximity to the valve house, the new or modified structures do not significantly detract from the valve house's historical setting. Therefore, the Southwest Valve House appears eligible for the NRHP and CRHR.

The other structures on the Tesla Portal site including the Tesla Portal Manifold Structure, the Caretaker's Cottage, the Caretaker's Garage, the Chlorinator Building, the Pump House/Equipment, Northwest Valve House, the Office/Storage Building, and the Water Tanks were found not to be eligible for either the NRHP or CRHR. These structures are not eligible for the NRHP or CRHR because they either are less than 45 years old, lack integrity, and/or lack historical significance.

Thomas Shaft Facility

The Thomas Shaft site includes a modern building, other recently constructed or installed tanks, pumps, valves, part of a wide gravel-covered road, and the two original Thomas Shafts, the construction shaft and the vent shaft, with depths of 350 and 300 feet, respectively (Shaw pers. comm., 2008). No historic architectural resources were identified at the Thomas Shaft site.

There are a total of five "access" or construction shafts associated with the Coast Range Tunnel: Thomas, Mitchell, Mocho, Valley, and Indian Creek (SFPUC, 2005). These five shafts were built during the years 1927-1933, with most construction occurring during 1928, and vary in depth from 254 to 823 feet (SFPUC, 2005). Along with the four portals, they provided 14 faces from which material could be excavated. At the bottom of each shaft, a crosscut had to be driven at right angles to the aqueduct, 95 feet to the centerline of the first tunnel to be dug and 80 feet to the parallel tunnel planned for the future. From the north end of each crosscut, the aqueduct tunnel was driven in both directions (City and County of San Francisco, 2007). The Thomas Shaft construction shaft is 350 feet deep, 50 feet deeper than the Thomas Shaft ventilation shaft to allow for the use of "muck trolleys" in the construction of the tunnel. The surface area around the Thomas Shaft construction shaft has modern pipes on the interior and exterior, placed by LLNL Site 300 in 1987 and the early 1990s (Shaw pers. comm., 2008). The only above-ground portion of the shaft is a very low white cover, which is not original.

The Thomas Shaft ventilation shaft is 300 feet deep and was used for ventilation and pressure relief from about 1932 through c. 1995-2000 (Shaw pers. comm., 2008) when the new facility was built and likely altered it. Recent modifications have resulted in the alteration of the ventilation shaft original function. The ventilation shaft is now used for water sampling and occasional water treatment with sodium chloride (Shaw pers. comm. 2008). The ventilation shaft is located on the southeast side of the exterior facility under the "tank cover," which is not original. The tank cover was placed over the ventilation shaft after construction of the new chlorination facility. The ventilation shaft was once maintained in a separate building. This building no longer exists (Shaw pers. comm. 2008).

A field survey conducted in 2004 for the SFPUC's Thomas Shaft Roadway Improvement Project resulted in the identification of one historic-period resource, more than 50 years old that was within the roadway improvement project's APE (Marken, 2007). The site was given the field designation S-01 and consisted of six cement foundations and an excavation bucket. The foundations and machinery identified were considered to be associated with the excavation of the original Thomas Shaft. S-01 is located approximately 50 feet from the proposed project at the Thomas Shaft site.

Significance and Integrity: The two original Thomas Shafts are each estimated 2-by 2-foot openings in the ground that extend approximately 300 and 350 feet beneath the surface. The construction of the large modern building and facilities and the lack of association and historic setting indicate that the shafts are not potentially eligible for listing in the CRHR. The Thomas Shaft facility's period of significance is 1928-1930, when it was constructed. The location of the Thomas Shaft original facility is nearly unrecognizable from its original setting, and almost all of the original, historic facilities, structures, and features have been altered or removed.

The Thomas Shaft facility does not appear to be eligible under the NRHP Criterion A (events) or the CRHR 1 (events). The shafts were built to aide in the construction of the Coast Range Tunnel which is associated with the building of the larger Hetch Hetchy system and later used as access points along the tunnel. Along the shafts are components of the Coast Range Tunnel, the Thomas Shaft has played a minor role in the delivery of water through the tunnel and only has potential significance as on of may contributing elements of the Coast Range Tunnel, if the tunnel itself was considered a historical resource. However, this resource does not have importance for its association with the delivery of Hetch Hetchy water and, therefore, they are not directly associated with the Hetch Hetchy system.

The Thomas Shaft facility does not appear to be eligible under the NRHP Criterion B (person) or CRHR 2 (person). Research indicates that the Thomas Shaft facility has no direct association with any significant person (GANDA, 2008a).

The Thomas Shaft facility does not appear to be eligible under the NRHP Criterion C (architecture/workmanship) or CRHR Criterion 3 (architecture/workmanship). The shafts are utilitarian shafts that were constructed to aid in the construction of the Coast Range Tunnel and its maintenance, and as such, they exhibit no exemplary style, craftsmanship, construction techniques, or engineering, and are not the work of a master architect or engineer.

The Thomas Shaft facility does not retain integrity as physical alteration is apparent and modern modifications have also changed the actual function of the shafts from their original use. The Thomas Shaft facility maintains integrity of location, as the shafts have not been moved. However, the design, workmanship, materials, feeling, and setting have been altered and compromised since most of the original materials of the shafts have been altered and the shafts are no longer serving the same function. In summary, features at the Thomas Shaft project site are not eligible under any of the NRHP or CRHR criteria.

4.7.2 Regulatory Framework

Federal

National Historic Preservation Act of 1966 (16 U.S.C. 470)

The National Historic Preservation Act (NHPA) was enacted to encourage the preservation and wise use of the country's historic resources, and establishes the policy of the U.S. Government regarding historic preservation. The Act defines historic preservation to include "the protection, rehabilitation, restoration and reconstruction of districts, sites, buildings, structures, and objects significant in American history, architecture, archaeology, or culture." The Act includes several key provisions, including the establishment of the National Register of Historic Places.

National Register of Historic Places

The NHPA authorizes the Department of the Interior to establish, maintain, and expand the National Register of Historic Places (National Register or NRHP). The National Register, which is maintained by the National Park Service (NPS), is a compilation of cultural resources that have been nominated and accepted as having historic, architectural, archaeological, engineering, or cultural significance, at the national, state, or local level.

The majority of "consensus determinations" of NRHP eligibility occur when properties are evaluated by a State Historic Preservation Officer (SHPO) in conjunction with federal environmental review procedures. Formal eligibility determinations also occur when properties are nominated to the NRHP, but are not listed due to owner objection. The criteria for determining eligibility have been developed by the NPS. In general, structures and features must meet at least one of the National Register criteria, usually be at least 50 years old, and retain sufficient historic integrity to convey their significance. Furthermore, a property that is significant under one or more of the National Register criteria must also be associated with an important historical context and be significant within that historical context.

Although this is a CEQA-only project, the architectural resources are evaluated using both NRHP and CRHR criteria, as a professional standard. A cultural resource's historical significance is determined using the NRHP Criteria for Evaluation at 36 CFR 60.4, which states that the quality of significance in American history, architecture, archeology, engineering, and culture is present in districts, sites, buildings, structures, and objects that possess integrity of location, design, setting, materials, workmanship, feeling, and association, and

- Criterion A: that are associated with events that made a significant contribution to the broad patterns of our history
- Criterion B: that are associated with the lives of persons significant to our past
- Criterion C: that embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values; or that represent a significant and distinguishable entity whose components may lack individual distinction

- Criterion D: that have yielded or are likely to yield information important to prehistory or history

Further, to qualify for the NRHP, a resource must retain sufficient historic integrity to convey its significance. Although the evaluation of integrity is sometimes a subjective judgment, it must always be grounded in an understanding of the resource's physical features and how they relate to its significance. The seven aspects of integrity, as listed in National Register Bulletin 15 (NPS, 2002), are:

1. Location (the place where the historic property was constructed or the place where the historic event occurred)

2. Design (the combination of elements that create the form, plan, space, structure, and style of a property)

3. Setting (the physical environment of a historic property)

4. Materials (the physical elements that were combined or deposited during a particular period of time and in a particular pattern or configuration to form a historic property)

5. Workmanship (the physical evidence of the crafts of a particular culture or people during any given period of history or prehistory)

6. Feeling (a property's expression of the aesthetic or historic sense of a particular period of time)

7. Association (the direct link between an important historic event or person and a historic property)

Archaeologists generally evaluate archaeological resources using Criterion D, based on their potential to yield information. Criterion D emphasizes the importance of the information encompassed in an archaeological site rather than its inherent value as a surviving example of a particular architectural type or its historical association with an important person.

If a cultural resource is determined to be eligible for inclusion to the NRHP, then it is automatically eligible for the California Register of Historical Resources (CRHR; see below). If a resource does not meet the NRHP criteria, it may still be eligible under the CRHR.

State

California Environmental Quality Act

The California Environmental Quality Act (CEQA) Statute and Guidelines include procedures for identifying, analyzing, and disclosing potential adverse impacts on historical resources, which are resources listed in or formally determined eligible for the National Register, the California Register, or local registers. CEQA requires agencies that have projects that include discretionary actions, such as financing or approval of public or private projects, to assess the effects of the project on historical resources. If a project may result in significant effects on historical resources, alternative plans or mitigation measures must be considered.

CEQA defines a historical resource as a resource that meets any of the following criteria:

- A resource listed in, or determined to be eligible for listing in, the National Register of Historic Places or California Register of Historical Resources.

- A resource included in a local register of historical resources, as defined in Section 5020.1(k) of the Public Resources Code, unless the preponderance of evidence demonstrates that it is not historically or culturally significant.

- A resource identified as significant (e.g., rated 1-5) in a historical resource survey meeting the requirements of Public Resource Code Section 5024.1(g) (Department of Parks and Recreation Form 523b), unless the preponderance of evidence demonstrates that it is not historically or culturally significant.

- Any object, building, structure, site, area, place, record, or manuscript which a lead agency determines to be historically significant or significant in the architectural, engineering, scientific, economic, agricultural, educational, social, political, military, or cultural annals of California, provided the determination is supported by substantial evidence in light of the whole record. Generally, a resource is considered "historically significant" if it meets the criteria for listing on the California Register of Historical Resources (CEQA Guidelines Section 15064.5(a)), described below.

- A resource that is included on a local register to be historically or culturally significant even though it does not meet the other four criteria listed here (e.g., Article 10 of the San Francisco Planning Code).

Also considered a historical resource under CEQA are unique archaeological resources. CEQA Guidelines (Section 21083.2(g)) define a unique archaeological resource as a resource that meets any of the following criteria:

- Contains information needed to answer important scientific research questions and that there is a demonstrable public interest in that information.

- Has a special and particular quality such as being the oldest of its type or the best available example of its type.

- Is directly associated with a scientifically recognized important prehistoric or historic event or person.

Human remains are considered a separate category of cultural resource. The CEQA Guidelines (Section 15064.5(g)) describe the steps to be taken if human remains are accidentally discovered. In the event of accidental discovery or recognition of any human remains in any location other than a dedicated cemetery, the following steps should be taken:

(1) There shall be no further excavation or disturbance of the site or any nearby area reasonably suspected to overlie adjacent human remains until:

A. The coroner of the county in which the remains are discovered must be contacted to determine that no investigation of the cause of death is required, and

B. If the coroner determines the remains to be Native American:

1. The coroner shall contact the Native American Heritage Commission within 24 hours.

2. The Native American Heritage Commission shall identify the person or persons it believes to be the most likely descended from the deceased Native American.

3. The most likely descendant may make recommendations to the landowner or the person responsible for the excavation work, for means or treating or disposing of, with appropriate dignity, the human remains and any associated grave goods as provided in Public Resources Code Section 5097.98, or

(2) Where the following conditions occur, the landowner of his authorized representative shall rebury the Native American human remains and associated grave goods with appropriate dignity on the property in a location not subject to further subsurface disturbance.

A. The Native American Heritage Commission is unable to identify a most likely descendent or the most likely descendant failed to make a recommendation within 48 hours after being notified by the commission.

B. The descendant identified fails to make a recommendation; or

C. The landowner or his authorized representative rejects the recommendation of the descendant, and the mediation by the Native American Heritage Commission fails to provide measures acceptable to the landowner.

California Register of Historical Resources

The California Register of Historical Resources (California Register or CRHR) is a statewide program that is similar to the National Register . It consists of a compilation of cultural resources that are significant within the context of local, California, or national history, but not necessarily history germane to other states. All resources listed in or formally determined eligible for the National Register are also eligible for the California Register, as are properties designated under municipal or county ordinances. A resource is eligible for listing in the California Register if it meets any of the following criteria for listing at the local, state, or national level and retains integrity:

1. Is associated with events that have made a significant contribution to the broad patterns of California's history and cultural heritage.

2. Is associated with the lives of persons important to our past;

3. Embodies the distinctive characteristics of a type, period, region, or method of construction, or represents the work of an important creative individual, or possesses high artistic values;

4. Has yielded, or may be likely to yield, information important in prehistory or history (Public Resources Code, Section 5024.1, Title 14 CCR, Section 4852).

The California Register's definition of integrity and its special considerations for certain properties differ slightly from the National Register. Integrity is defined as "the authenticity of a historical resource's physical identity evidenced by the survival of characteristics that existed during the resource's period of significance" (California Office of Historic Preservation, 2006). The period of significance is the date or span of time within which significant events transpired, or significant individuals made their important contributions. Simply put, the resources must retain enough of their historic character or appearance to be recognizable as historical resources and to convey the reasons for their significance. A resource that has lost its historic character or appearance may still have sufficient integrity for the California Register if, under Criterion 4, it maintains the potential to yield significant scientific or historical information or specific data. The California Register's special considerations (i.e., CRHR eligibility for non-standard properties) for certain property types are limited to: (1) moved buildings, structures, or objects; (2) historical resources achieving significance within the past 50 years; and, (3) reconstructed buildings.

California Public Resources Code

California Public Resources Code Section 5097.5 prohibits excavation or removal of any "vertebrate paleontological site, or any other archaeological, paleontological, or historical feature, situated on public lands, except with the express permission of the public agency having jurisdiction over such lands." Public lands are defined to include lands owned by or under the jurisdiction of the state or any city, county, district, authority, or public corporation, or any agency thereof. Section 5097.5 also states that any unauthorized disturbance or removal of archaeological, historical, or paleontological materials or sites located on public lands is a misdemeanor. Section 30244 requires reasonable mitigation for impacts on paleontological resources that occur as a result of development on public lands.

Section 5097.98 of the California Public Resources Code prohibits obtaining or possessing Native American artifacts or human remains taken from a grave or cairn, and sets penalties for such acts. Additionally, Section 5097.98, as amended by Assembly Bill 2641, includes the following provisions:

(a) Whenever the commission receives notification of a discovery of Native American human remains from a county coroner pursuant to subdivision (c) of Section 7050.5 of the Health and Safety Code, it shall immediately notify those persons it believes to be most likely descended from the deceased Native American. The descendants may, with the permission of the owner of the land, or his or her authorized representative, inspect the site of the discovery of the Native American human remains and may recommend to the owner or the person responsible for the excavation work means for treatment or disposition, with appropriate dignity, the human remains and any associated grave goods. The descendants shall complete their inspection and make their recommendation within 48 hours of their notification by the

Native American Heritage Commission. The recommendation may include the scientific removal and nondestructive analysis of human remains and items associated with Native American burials.

(e) Whenever the commission is unable to identify a descendant, or the descendant identified fails to make a recommendation, or the landowner or his or her authorized representative rejects the recommendation of the descendants and the mediation provided for in subdivision (k) of Section 5097.94 fails to provide measures acceptable to the landowner, the landowner or his or her authorized representative shall re-inter the human remains and items associated with Native American human remains with appropriate dignity on the property in a location not subject to further subsurface disturbance.

City and County of San Francisco

Planning Code Article 10

Article 10 of the San Francisco Planning Code describes procedures regarding the preservation of sites and areas of special character or special historical, architectural, or aesthetic interest or value, such as officially designated city landmarks and buildings included within locally designated historic districts.

Planning Department, CEQA Review Procedures for Historic Resources

The San Francisco Planning Department prepared the CEQA Review Procedures for Historic Resources (Draft, March 31, 2008, subject to change; also referred to as San Francisco Preservation Policy Bulletin No. 16) to provide direction and guidance for the environmental review of historical resources. San Francisco Preservation Policy Bulletin No. 16 provides direction to determine whether the potential property fits the definition of an "historical resource" as defined in the CEQA Statutes and Guidelines. Three categories of properties are defined as follows:

Category A.

- Category A.1. Resources listed in or formally determined to be eligible for the California Register

- Category A.2. Resources listed on adopted local registers, and properties that have been determined to appear eligible, or may become eligible, for the California Register.

Category B. Properties requiring further consultation and review.

Category C. Properties determined not to be historical resources, or properties for which the city has no information indicating that the property is a historical resource.

4.7.3 Impacts

Significance Criteria

The City and County of San Francisco has not formally adopted significance standards for impacts related to cultural resources, but generally considers that implementation of the proposed project would have a significant impact on cultural resources if it were to:

- Cause a substantial adverse change in the significance of a historical resource as defined in CEQA Guidelines Section 15064.5, including those resources listed in Article 10 or Article 11 of the San Francisco Planning Code
- Cause a substantial adverse change in the significance of a unique archaeological resource pursuant to Section 15064.5 of the CEQA Guidelines
- Directly or indirectly destroy a unique paleontological resource or site or unique geological feature
- Disturb any human remains, including those interred outside of formal cemeteries

Areas of No Impact

The Thomas Shaft project site does not contain cultural resources within the project area. Therefore, implementation of the proposed project at the Thomas Shaft site would not demolish or alter individual historical resources or disturb a contributor to a historic district. No impact would occur in respect to this significance criterion.

Articles 10 and 11 of the San Francisco Planning Code pertain to officially designated city landmarks and buildings included within designated historic districts in San Francisco. As the proposed project does not propose improvements in San Francisco, there are no designated city landmarks or properties that contribute to designated historic districts in the project site vicinities and therefore, this ordinance would not apply to the proposed project.

The proposed project (Tesla Portal and Thomas Shaft) would not result in any operational impacts in regards to cultural resources because the operational functionality of the proposed facilities (e.g., water treatment) would have no effect on historical, archaeological or paleontological resources.

Approach to Analysis

The cultural resources analysis evaluates potential short-term and long-term impacts associated with the construction and operation of the proposed project at the Tesla Portal and Thomas Shaft sites in regards to paleontological resources, archaeological resources and historic architectural resources. In general, implementation of the proposed project would not result in significant direct and/or indirect long-term or short-term effects on known cultural resources, given compliance with existing regulations and established project procedures, Standard Construction Measure # 9, and the implementation of mitigation measures described in Section 5.0.

Area of Potential Effects

Cultural resources investigations conducted at the Tesla Portal and Thomas Shaft sites resulted in the identification of an area of potential effects (APE) (refer to Figures 4.7-1 and 4.7-2) for each site. The APE is divided into horizontal and vertical APEs for both archaeological and architectural resources. The horizontal APE consists of the footprint of project-related ground disturbance, including areas that would be excavated, graded, or modified in any way. The vertical APE includes the subsurface areas that could be impacted by project-related construction and other activities. Major ground disturbance has previously occurred at both project locations in conjunction with the original pipeline and building foundation construction. The APE for the built environment also considers above-ground, construction-related impacts and visual disturbances to potentially historic settings known and potential historical resources; therefore, the parameters of the architectural APE are equal to the developed site area of each project site. Following is a description of the APEs for the project sites.

Tesla Portal Site

The horizontal architectural APE for the Tesla Portal site encompasses the entire project site (approximately 52 acres), including the surface area west of the Tesla Portal facility. However, the water facility resources located below ground west of the manifold, are not included as part of the architectural APE.[2] The horizontal archaeological APE encompasses the proposed construction (3 acres) and staging (9 acres) areas for a total of approximately 12 acres. The maximum vertical archaeological APE anticipated at the Tesla Portal site is 20 feet below ground surface which, based on old construction drawings, would exceed the historic depth of ground disturbance (14 feet) by 6 feet.

Thomas Shaft Site

The horizontal architectural and archaeological APEs for the Thomas Shaft site are located on the developed portion of the site, which totals approximately 1 acre. The maximum depth of disturbance proposed at the Thomas Shaft site is approximately 4 feet, for the installation of a 150 feet by 3 feet by 3 feet underground pipeline (refer to Chapter 3, Project Description). Based on old construction drawings, the previous depth of disturbance at the Thomas Shaft site was approximately 7 feet. The grade also varies plus or minus 3 feet, for a total estimated prior disturbance of 10 feet. Therefore, the proposed depth of disturbance would be close to but not exceed the historic depth of disturbance at the Thomas Shaft site.

[2] The Coast Range Tunnel is not in the APE for this project because the project would have no effect on the tunnel.

Construction Impacts

Paleontological Resources

Impact 4.7-1: Potential to disturb or destroy paleontological resources. (Tesla Portal: PSM; Thomas Shaft: PSM)

Site reconnaissance at the Tesla Portal and Thomas Shaft sites did not encounter any paleontological resources (GANDA, 2008b). However, as described previously, the following paleontologically sensitive geologic units were observed in or adjacent to both sites: late Pleistocene alluvium, Miocene San Pablo Group sandstones, and late Mesozoic Franciscan Complex sediments. Furthermore, numerous fossil resources have been discovered within 5 miles of each site, including important specimens.

Tesla Portal Site

The maximum depth of proposed ground disturbance at the Tesla Portal site would be 20 feet below ground surface, which would exceed historic ground disturbance of approximately 14 feet by 6 feet. In addition, the proposed improvements to the access road would require grading. Consequently, there is a high potential that underlying native sediments and bedrock within the Tesla Portal APE containing paleontologically sensitive geologic units would be disturbed during project construction. Even in areas where prior ground disturbance has occurred, project-related ground-disturbing activities could vertically or horizontally disturb sediments beyond the area of previous ground disturbance. The potential to disturb native sediments and bedrock containing paleontologically sensitive geologic units within the Tesla Portal APE could result in potentially significant impacts to paleontological resources.

Potentially significant impacts on paleontological resources would be reduced to a less-than-significant level by monitoring construction, relocating construction work away from the area if a paleontological resource is identified, and having the site inspected by a qualified paleontologist (Mitigation Measures 4.7-1a and 4.7-1b).

Thomas Shaft Site

Original Thomas Shaft construction drawings show a prior excavation depth of approximately 7 feet with a grade variation of plus or minus 3 feet, for a total estimated maximum prior disturbance of 10 feet and a minimum of 4 feet. The depth of the proposed ground disturbance at this site would be associated with the proposed 12-inch pipeline and would extend to approximately 4 feet below ground surface, which would come near but not exceed the depth of prior ground disturbance. Although the probability of potential impacts to paleontological resources is low, if such resources are encountered during project ground-disturbing activities, they could be inadvertently damaged or destroyed, which would be a significant impact. Implementation of Mitigation Measure 4.7-1b, which, among other features, requires suspension of construction work, relocating construction away from the area if a paleontological resource is identified, and having the site inspected by a qualified paleontologist, would reduce potential impacts to less than significant.

Archaeological Resources

Impact 4.7-2: Potential to disturb or destroy unknown prehistoric or historic-era archaeological resources or human remains. (Tesla Portal: PSM; Thomas Shaft: PSM)

Based on GANDA's archaeological investigation, which included a records search, field survey, historic map research, and personal communication with project engineers, no evidence was found that prehistoric archaeological resources are present within or adjacent to the APE for the Tesla Portal or Thomas Shaft sites. In addition, no evidence was found regarding archaeological deposits relating to the construction of the San Joaquin Pipelines, Thomas Shaft or Tesla Portal facilities. Furthermore, the potential for encountering intact buried archaeological deposits is low due to the level of previous disturbance and the soils present beneath the surface at each site.

The geomorphology of the Tesla Portal site, including the soils and landforms present, was assessed to determine the potential for buried prehistoric archaeological resources between 14 and 20 feet below the surface. As previously mentioned, the maximum depth of proposed ground disturbance at the Tesla Portal site would be 20 feet below ground surface (for excavation of the existing pipelines), which would exceed historic ground disturbance of approximately 14 feet by 6 feet. In addition, grading would be required for the proposed improvements to the access road. Grading for the access road would be shallow, but would be in an area that has not been previously disturbed to the extent the rest of the Tesla Portal site has been disturbed. Proposed buildings would be constructed on concrete pads with minimal grading. The proposed construction activities would have the potential to encounter native soils during excavation required for the pipelines and grading for the access road. However, geological information suggests that the landforms where grading would occur are Pleistocene alluvial deposits that are 10,000 years and older. Buried prehistoric archaeological deposits in the region are found within mid- to late Holocene-age alluvial deposits, which are less than 8,000-5,000 years old. Therefore, it is unlikely that the Tesla Portal APE is sensitive for the presence of deeply buried archaeological resources or prehistoric living surfaces (paleosols).

Similarly, the Thomas Shaft project site has a prior excavation depth of approximately 7 feet with a grade variation of plus or minus 3 feet, for a total estimated maximum prior disturbance of 10 feet and a minimum of 4 feet. The depth of the proposed ground disturbance at this site would be approximately 4 feet below ground surface, which would come near but not exceed the depth of prior ground disturbance. In addition, similar to Tesla Portal, the Thomas Shaft site is also underlain by Pleistocene alluvial deposits. As such, there is a very low sensitivity for the presence of buried archaeological deposits at the Thomas Shaft site.

There are no previously recorded prehistoric or historic-era archaeological resources within the APEs at the two project sites and no surface indications of these types of resources. Nevertheless, there remains the potential for encountering unanticipated subsurface archaeological deposits or human remains because their subsurface presence cannot be conclusively ruled out. Impacts to

unanticipated subsurface archaeological deposits or human remains would be a potentially significant impact without the implementation of mitigation measures.

If concentrations of prehistoric or historic-period materials are encountered during ground-disturbing work at the either the Tesla Portal or Thomas Shaft site, it is recommended that all work halt within 100 feet of the find until a qualified archaeologist can evaluate the find and make recommendations (Mitigation Measure 4.7-2a). If human remains are encountered, work in the immediate vicinity should stop and the County Coroner should be notified immediately. At the same time, a qualified archaeologist should be contacted to evaluate the finds. If the human remains are of Native American origin, the Coroner must notify the Native American Heritage Commission within 24 hours of this identification (Mitigation Measure 4.7-2b). Implementation of Mitigation Measures 4.7-2a and 4.7-2b would reduce potentially significant impacts to a less than significant level.

Historical Architectural Resources

Impact 4.7-3: Potential to cause a substantial adverse change in the significance of a historical resource. (Tesla Portal: PSM; Thomas Shaft: N/A)

Based on the cultural resources investigation for the project, the Southwest Valve House and the SJPLs No. 1 and No. 2 appear to be eligible for listing in the NRHP and/or the CRHR.

The Southwest Valve House appears to be eligible for listing in the NRHP under Criterion A and CRHR under Criterion 1 (URS-ATS Joint Venture, 2008). The SJPLs No. 1 and No. 2 appear to be eligible for listing on the NRHP under Criterion A and CRHR under Criterion 1 at the local level due to their association with the development of the San Francisco water system. Additionally, SJPL No. 1 appears to be eligible under NRHP Criterion C and CRHR Criterion 3 for the innovative engineering techniques used by the Youdall Company during its construction (URS-ATS Joint Venture, 2008).

SJPLs No. 1 and No. 2 would not be significantly altered as a result of the proposed project. SJPLs No. 1 and No. 2 would be connected to a new upstream manifold that would combine the flow and redirect water to the proposed UV reactors. Upon UV treatment, the water would be directed to an outlet manifold (downstream), which would tie back into the existing SJPLs. Construction of the manifolds would require cutting the SJPLs at the upstream and downstream connection points, and the new manifolds would be constructed at the SJPL tie-in point. The upstream manifold would include a line-sized isolation valve in each pipeline, which would include connection point for the future SJPL segment, similar to the existing manifold. The installation of the new manifolds would result in the abandonment of approximately 400 feet of SJPL No. 1 and No. 2. The pipeline segments would be capped, reburied and left in place upon completion of the proposed project.

Although the proposed work at Tesla Portal would result in minor modifications to the SJPLs No. 1 and No. 2, project-related activities would not have a significant adverse effect on this resource for the following reasons:

1) Project-related activities would not have an adverse effect on the SJPLs No. 1 and No. 2 because the proposed modifications to the resources would not change the characteristics of the pipelines that make them eligible for the NRHP/CRHR.

2) The proposed project's direct impact to SJPL No. 1 and No. 2 is limited to replacement of 300 feet of those structures, which are a total of 47.5 miles long each. Most of the SJPLs No. 1 and No. 2 would not be impacted by this project, including multiple points of the pipeline located above ground across the San Joaquin Valley. This change is thus a relatively minor alteration compared to the overall dimensions of the resources that does not diminish the overall historic integrity of the historical resources such that it cannot convey its significance.

3) There would be no indirect impact, including visual effects, on any portions of the SJPLs No. 1 and No. 2, as most of the work would occur on portions of the SJPLs that are located below ground surface.

4) The modifications to SJPLs No. 1 and No. 2 would not change the way the Hetch Hetch system operates and functions as a whole.

5) The overall modifications to SJPLs No. 1 and No. 2 are comprised of technology upgrades and facility infrastructure activities that are small in scale compared to the size of the Hetch Hetchy system.

In addition to SJPLs No. 1 and No.2, the NRHP/CRHR eligible Southwest Valve House would be in close proximity (25 feet) to above ground construction activities at the Tesla Portal site, but would not be directly modified by project activities. Construction near the Southwest Valve House would include the installation of a steel and concrete enclosure to be placed around the new Portal Manifold, as well as backfilling the enclosure. Project-related activities would not result in changes to the significant architectural features of the Southwest Valve House that make it a potentially eligible for the NRHP/CRHR, or change the relationship between the Southwest Valve House and the Portal Manifold. In addition, the installation of the steel and concrete enclosure would not result in physical modifications or significant visual impacts to the Southwest Valve House.

The installation of the proposed structures as part of the project at the Tesla Portal site would not have a significant direct effect on the Southwest Valve House, thus the project would not cause a substantial adverse change to the historical resource. In addition, construction related vibration would not be substantial enough to damage the Southwest Valve House (refer to Section 4.10, Noise and Vibration). However, given the proximity of construction activities to the Southwest Valve House (25 feet), accidental damage to the building during construction cannot be ruled out,

and therefore would be a potentially significant impact. Implementation of Mitigation Measure 4.7-3 (Architectural Resources Protection Plan) requires preparation and implementation of an architectural resources protection plan that specifies procedures for protecting historical resources during construction, and also requires a temporary protective barrier around the Southwest Valve House to prevent physical damage. With implementation of this mitigation measure, impacts would be reduced to a less-than-significant level.

The installation of the proposed project would not have a significant effect on the SJPLs No. 1 and No. 2, and therefore the project would not cause a substantial adverse change to the historical resources. However, construction-related activity associated with modifications to the SJPLs No. 1 and 2 would be expected to exceed the 0.2 in/sec threshold for sensitive structures (refer to Section 4.10, Noise and Vibration), and result in a potentially significant impact. Implementation of Mitigation Measure 4.10-2, which requires the construction contractor perform construction in such a manner as to maintain the structural integrity of the pipelines, would reduce potential impacts due to vibration to a less-than-significant level.

Operational Impacts

The proposed project would not result in operational impacts related to cultural resources as described above.

4.8 Traffic, Transportation, and Circulation

4.8.1 Setting

Regional and Local Roadways

Characteristics of local intersections and roadways in the project vicinities are described below and shown on Figure 4.3-1a, and Figure 4.3-1b.

Tesla Portal Site

Interstate 580 (I-580) is an east/west freeway that extends from the San Francisco Bay Area, through the Altamont Pass, and connects to Interstate 5 (I-5), south of the City of Tracy. This interstate currently has four lanes in the segments closest to the project sites.

State Route 132 (SR 132) is a four-lane, east/west highway that traverses the southern part of San Joaquin County between I-580 and Stanislaus County; it eventually merges to two lanes. The portion of SR 132 closest to the Tesla Portal project site is a four-lane highway.

West Vernalis Road is an east/west roadway (local collector) that serves as a frontage road to I-580 and the main access route for the residential community of Chrisman, the Tesla Portal site, and three residences near the Tesla Portal site. West Vernalis Road has one lane in each direction. It begins at its intersection with South Chrisman Road to the east and public access ends at the Tesla Portal site's unpaved access road to the west. Although public access on West Vernalis Road ends at the Tesla Portal site, access to a private property located west of the site is provided via a right-of-way easement through SFPUC property.

South Chrisman Road is a north/south roadway (local collector) that serves the area south of I-580, including residential land uses, the Tracy Golf and Country Club and the Tesla Portal site. South Chrisman Road provides access to I-580, eastbound and westbound.

Thomas Shaft Site

Corral Hollow Road is an east/west arterial roadway in San Joaquin County, with one lane in each direction. Corral Hollow Road runs between the City of Livermore to the east and I-580 to the west. Corral Hollow Road becomes Tesla Road once it crosses from San Joaquin County into Alameda County.

Thomas Shaft Road is a gated, unpaved, gravel north/south roadway in San Joaquin County, with one 18-foot-wide lane leading to the Thomas Shaft site. The road is entirely within SFPUC property boundaries. Corral Hollow Road provides access to Thomas Shaft Road. There are future plans to improve Thomas Shaft Road that include replacing culverts and paving the roadway (see Section 4.15). The planned improvements will improve access to the Thomas Shaft Facility during the winter months.

Existing Traffic Volumes

Tesla Portal Site

Interstate I-580: Average daily trips on I-580, near the Tesla Portal site, are approximately 31,550 vehicles per day, or 328 vehicles per lane per hour (Caltrans, 2007). Of this traffic, approximately 16 percent of I-580's traffic volume consists of truck trips (Caltrans, 2007). According to the Caltrans Highway Design Manual, a four-lane highway (two-lanes in each direction) has a design capacity of 1,000 to 1,200 vehicles per lane per hour. Therefore, the portion of I-580 near the project sites is operating below its designed traffic volume capacity.

State Route 132: Traffic volumes on SR 132 are relatively light. The average daily traffic volume is approximately 19,500 vehicles per day, or 203 vehicles per lane per hour (Caltrans, 2007). Truck traffic represents more that 25 percent of the traffic volume (Caltrans, 2007). According to the Caltrans Highway Design Manual, a four-lane highway (two-lanes in each direction) has a design capacity of 1,000 to 1,200 vehicles per lane per hour. Therefore, the portion of SR 132 near the project sites is operating below its designed traffic volume capacity.

West Vernalis Road: Neither San Joaquin County or the San Joaquin County of Governments (SJCOG) have traffic counts for West Vernalis Road. Traffic counts were extrapolated based on the existing surrounding land uses (residential) and methodology provided in the Institute of Traffic Engineer's (ITE) Trip Generation Manual 7th Edition. Using this methodology, average daily traffic volume on West Vernalis Road, north of its intersection with South Chrisman Road is estimated at approximately 400 vehicles per day. According to the SJCOG, a local collector road has a traffic volume capacity of approximately 10,000 vehicles per day. Therefore, West Vernalis Road is operating below its designed traffic volume capacity.

South Chrisman Road: Neither San Joaquin County or the SJCOG have traffic counts for portions of South Chrisman Road nearest to the Tesla Portal site. Traffic counts were extrapolated based on the existing surrounding residential and recreational (golf course) land uses and methodology provided in the ITE Trip Generation Manual 7th Edition. Using this methodology, average daily traffic volume on South Chrisman Road is estimated at approximately 1,140 vehicles per day. According to SJCOG, a local collector road has a traffic volume capacity of approximately 10,000 vehicles per day. Therefore, South Chrisman Road is operating below its designed traffic volume capacity.

Thomas Shaft Site

Corral Hollow Road: In the vicinity of the Lawrence Livermore National Laboratory (LLNL) Site 300, the average daily traffic volume on Corral Hollow Road is 3,006 vehicles per day west of the LLNL Site 300, and 3,474 vehicles per day east of LLNL Site 300 (CCSF Planning Department, 2007). Corral Hollow Road has a capacity of approximately 10,000 vehicles per day and, therefore, is operating below its designed traffic volume capacity.

Thomas Shaft Road: Thomas Shaft Road is a private access road with limited capacity. Traffic volume along Thomas Shaft Road is minimal. This road serves the SFPUC Thomas Shaft

Facility, and a portion of this road also serves as the only access for one rural residence. Traffic counts were extrapolated based on the existing surrounding land uses (one residence), methodology provided in the ITE Trip Generation Manual 7th Edition (ITE, 2003), and on the average number of trips to the site by SFPUC personnel per day. Using this methodology, the average daily traffic volume on Thomas Shaft Road is estimated at approximately 11 vehicles per day. According to the SJCOG, a rural two-lane road has a traffic volume capacity of approximately 600 vehicles per lane per hour, and therefore Thomas Shaft Roadway is operating below its designed traffic volume capacity.

Existing Site Access and Onsite Circulation

Tesla Portal Site

Access to the existing Tesla Portal site is through an existing paved access road that connects to West Vernalis Road. The existing access road leads to the existing Tesla Portal facilities, which include a paved parking lot. There are a number of other unpaved access roads on the site that either cross or run along the perimeter of the property. However, the paved access road that connects to West Vernalis Road is the site's main access.

Thomas Shaft Site

Access to the Thomas Shaft site is through the unpaved, gravel 1.5-mile Thomas Shaft Road, off Corral Hollow Road. The Thomas Shaft site does not have a formal parking lot, but the paved area next to the existing building is large enough to provide temporary parking, and also along the roadway. These parking areas are utilized for maintenance and operation of the current facility.

The San Joaquin County Department of Public Works is planning a roadway safety improvement project to install guardrails on Corral Hollow Road approximately two miles west of I-580. Anticipated schedule of completion is end of 2008 or early 2009. In addition, SFPUC is planning to improve Thomas Shaft Road from its intersection with Corral Hollow Road to the Thomas Shaft Facility. Anticipated schedule of completion for the Thomas Shaft Roadway Improvement Project is January 2009.

Transit Service

The project sites are located near the City of Tracy, which provides two options for transit (bus) service, the Tracer (local system) and the San Joaquin Regional Transit District (intercity fixed-route, flexible fixed route and commuter express). Given the rural location of the project sites, there are no transit routes in the immediate vicinity that would serve the proposed project.

Bicycle and Pedestrian Network

San Joaquin County has identified bicycle routes as an energy efficient, non-polluting form of transportation and has included them in the region's multi-modal transportation system. According to the County's General Plan 2010, specific routes for bikeways (as well as

pedestrians) will be revised as future development occurs. Most planned bicycle routes in the County have not been constructed, and the County is giving the construction of "non-motorized travel" facilities the highest priority. Pedestrian facilities generally include sidewalks, crosswalks, and pedestrian signals. Given the rural location of the project sites, there are no bicycle or pedestrian facilities in the immediate vicinity that would serve the proposed project.

4.8.2 Regulatory Framework

Transportation analysis in California is guided by policies and standards set at the state level by the California Department of Transportation (Caltrans), as well as by local jurisdictions (San Joaquin County). There are no federal regulations that address transportation impacts associated with the proposed project. Both Caltrans and San Joaquin County generally assess the impact of long-term, not short-term, traffic conditions.

Plans and policies related to transportation aim to plan for and accommodate future growth and the vehicular, transit, pedestrian, and bicycle travel demand associated with that growth. Policies regarding traffic service levels apply to long-term, not short-term, traffic conditions. These policies generally specify maintaining a Level of Service[1] (LOS) of LOS C or LOS D on major streets during the peak periods of traffic. Mitigation measures would be required if project-related traffic impacts would result in an LOS exceeding the local jurisdiction's threshold.

San Joaquin County

San Joaquin County's General Plan 2010 does not have an established LOS threshold of significance.

The SJCOG Regional Transportation Plan (2007) establishes the LOS standards for roadways included in the Congestion Management Program (CMP) network. The CMP includes, among other roadways, I-580 and SR 132 as CMP roadways and the SJCOG establishes LOS E as the performance standard for these roadways. The LOS standards of roadway networks vary by roadway segment, although these standards do not generally apply to impacts resulting from construction, rehabilitation, or maintenance of facilities that impact the CMP network.

4.8.3 Impacts

Significance Criteria

The City and County of San Francisco (CCSF) has not formally adopted significance standards for impacts related to traffic, transportation and circulation, but generally considers that implementation of a proposed project would have a significant impact if it were to:

[1] LOS is a qualitative description of a facility's performance based on average delay per vehicle, vehicle density, or volume-to-capacity ratios. Levels of service range from LOS A, which indicate free-flow or excellent conditions with short delays, to LOS F, which indicate congested or overloaded conditions with extremely long delays.

- Cause an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume-to-capacity ratio on roads, or congestion at intersections)
- Exceed, either individually or cumulatively, a level of service standard established by the county congestion management agency for designated roads or highways (unless it is practical to achieve the standard through increased use of alternative transportation modes)
- Result in a change in air traffic patterns, including either an increase in traffic levels, an obstruction to flight, or a change in location, that results in substantial safety risks
- Substantially increase hazards due to a design feature (e.g., sharp curves at dangerous intersections) or incompatible uses, or interfere with existing transportation systems (including vehicular, pedestrian, and bicycle networks), causing substantial alterations to circulation patterns or major traffic hazards
- Result in inadequate emergency access
- Result in inadequate parking capacity that could not be accommodated by alternative solutions
- Conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., conflict with policies promoting bus turnouts, bicycle racks, etc), or cause a substantial increase in transit demand that cannot be accommodated by existing or proposed transit capacity or alternative travel modes

Areas of No Project Impact

Several of these criteria are *not applicable* to the proposed project, as there is no potential for the impact to occur. Project implementation would not result in inadequate parking capacity. The Tesla Portal site has paved areas available, and the Thomas Shaft site has unpaved areas available that would sufficiently accommodate employee, visitor and delivery vehicles during project construction and operation. The project sites would not change air traffic patterns resulting in a substantial safety risk because neither site is located near an airport. Additionally, the project would not involve installation of structures that could interfere with airspace.

Access to the Tesla Portal site would be provided through the existing paved access road, which connects to West Vernalis Road. The existing access road would be widened (17 to 20 feet) and re-paved as part of the proposed project. The project site would include two access roads. The main access road would connect to a circulation loop that would provide access to the proposed Office/Control Building, as well as the Chemical Process Building and Ultraviolet (UV) Building. The circulation loop would connect back to the main access road. An existing secondary access route that runs parallel to the eastern property boundary, would provide access to existing property owners that have an easement along the SFPUC right of way. A total of 19 parking spaces (including two accessible spaces for disabled parking) would be provided at the Tesla Portal site for employee and visitor parking. Access to the Thomas Shaft site would be provided

via the existing 1.5 mile Thomas Shaft Road, off Corral Hollow Road. Parking for the Thomas Shaft Facility is available at the existing Thomas Shaft Facility and would continue to be used during the construction and operation of the proposed facilities. These improvements would not result in inadequate emergency access at either site.

The project would not change the existing or planned transportation network in San Joaquin County and, therefore, would not include any design features that would increase the potential for traffic safety hazards, nor would the project conflict with policies, plans, or programs related to transit, bicycle, or pedestrian travel. Project operation would not result in any increase in transit demand, nor is either site located in close proximity to any transit stops or routes. The project would not impair access to adjacent roadways and land uses for both general and emergency response traffic as well as for bicycles and pedestrians, nor would the project result in the displacement of on-street parking because project-related construction would be confined within existing SFPUC property. Therefore, the proposed project would have no impact with respect to these significance criteria.

Approach to Analysis

The analysis provided in this section assesses the potential transportation impacts associated with the implementation of the proposed project. This section evaluates the potential for short-term construction related impacts on roadways due to changes in roadway capacities or increases in construction related traffic, as well as long-term impacts due to the operation of new facilities at both project sites.

The impact assessment of construction related impacts assumes that that the contractor(s) for each project site would implement SFPUC Standard Construction Measure #5 (see Chapter 3, Project Description) for traffic, which specifies that each contractor prepare a traffic control plan to minimize traffic on any streets affected by construction of the proposed project. As appropriate, SFPUC or the contractor would consult with local traffic agencies. This transportation assessment assumes that if multiple contracts for work within a project are issued, each project would prepare a traffic control plan, as applicable to the situation.

Construction Impacts

Construction-related traffic impacts are not usually considered significant, because given their temporary nature, they are usually of limited duration. However, since construction of the proposed project at the Tesla Portal site could affect the local transportation network for a longer duration (approximately 24 months), its impacts could be determined to be potentially significant. Construction activities that affect roadway operations are typically regulated through permits and construction requirements to ensure acceptable levels of traffic flow during the period of traffic disruption. Construction best management practices, including the preparation of a traffic control plan, are required to be in place to ensure the safety of construction workers, motorists, bicyclists, and pedestrians throughout project construction.

Impact 4.8-1: Temporary reduction in roadway capacity and increased traffic delays (Tesla Portal: LS; Thomas Shaft: LS)

Project construction at the Tesla Portal site and the Thomas Shaft site would not result in temporary lane closures, road closures or detours, which could reduce the capacity of the main access routes that would serve the project sites and cause traffic delays. Construction at the project sites would be confined within SFPUC's existing right-of-way, and no construction (including construction staging) within public roadways would occur. Therefore, construction traffic would not result in the temporary reduction in traffic capacity on roadways within the vicinity of the project sites. In addition, implementation of SFPUC's Construction Measure #5 (traffic control plan) will address any potential traffic delays in the proximity of the project sites. This impact would be less than significant.

_____

Impact 4.8-2: Short-term traffic increases on roadways due to construction related vehicle trips (Tesla Portal: LS; Thomas Shaft: LS)

Tesla Portal Site

The access route for the Tesla Portal site includes I-580, Chrisman Road and West Vernalis Road. These access routes are operating at or below their designed traffic volume capacities. Construction activities associated with project activities at the Tesla Portal site would result in the temporary addition of approximately 25 to 30 daily construction-related round-trips (50 to 60 daily trips), for a duration of approximately 24 months. The temporary addition of 25 to 30 daily round-trips represents the anticipated amount of daily trips during the construction period and includes delivery trucks, as well as worker commuter trips.[2]

Additional truck trips would be required for at least four days for concrete pouring. Concrete required for mat foundations at the Tesla Portal site would result in 140 round-trips (280 trips in one day) for the UV Building, 120 trips (240 trips in one day) for the Chemical Process Building, 15 round-trips (30 trips in one day) for the Office/Control Building, and no more than 15 round-trips (30 trips in one day) for accessory components such as walls and vaults. Construction trips related to concrete delivery would occur on one day per each of these proposed facilities, and would be done on different days to reduce overall truck trips to the sites. The single day peak number of construction related trips at the Tesla Portal site would be 170 round-trips (340 trips). Refer to Table 4.8-1, Tesla Portal Site Construction-Related Trips.

[2] Worker commuter trips are generally regarded as peak hour trips. Peak hour trips are those trips that occur during peak traffic periods. Peak traffic periods are between 7:00 a.m. and 9:00 a.m. and 4:00 p.m. and 6:00 p.m.

TABLE 4.8-1
TESLA PORTAL SITE CONSTRUCTION-RELATED TRIPS

Type of Trips	Number of Daily Round-Trips	Duration
Daily Construction[1]	25 – 30	18 to 24 Months
Concrete Delivery Per Project Component[2]		
UV Building:	140	1 Day
Chemical Process Building:	120	1 Day
Office/Control Building:	15	1 Day
Accessory Components:	15	1 Day

[1] Daily construction trips are round-trips and include worker commuter trips.
[2] Concrete related trips would occur on a single day per project component.

Thomas Shaft Site

The access route for the Thomas Shaft site includes I-580, Corral Hollow Road and Thomas Shaft Road. Construction activities associated with the proposed project would result in the temporary addition of approximately five daily round-trips (10 truck trips per day) over a period of six months. Concrete required at the Thomas Shaft site would be very minimal (only to anchor the prefabricated enclosure for the valve head), which would result in only one daily round-trip (two trips for one truck load in one day). The single day peak number of construction related trips at the Thomas Shaft site is 6 round-trips (12 trips). Refer to Table 4.8-2, Thomas Shaft Site Construction-Related Trips.

TABLE 4.8-2
THOMAS SHAFT SITE CONSTRUCTION- RELATED TRIPS

Type of Trips	Number of Daily Round-Trips	Duration
Daily Construction[1]	5	6 Months
Concrete Delivery	1	1 Day
Prefabricated Enclosure for the Valve Head:	1	1 Day

[1] Daily construction trips are round-trips and include worker commuter trips.

The temporary addition of construction-related traffic would not represent a significant increase in traffic on the project sites' access routes. In addition, as part of the proposed project, SFPUC

would implement Construction Measure #5, which requires each construction contractor to prepare a traffic control plan that would minimize construction-related traffic on any streets affected by construction of the proposed project. As appropriate, the contractor would consult with local traffic and transit authorities. Based on the above, the proposed project impacts related to short-term traffic increases would be less than significant.

Potential cumulative traffic impacts, including the potential for overlapping Water System Improvement Program project activities and construction vehicles to affect regional traffic, are discussed in Section 4.15, Cumulative Effects.

Impact 4.8-3: Increased potential traffic safety hazards for vehicles, bicyclists, and pedestrians on public roadways during construction (Tesla Portal: LS; Thomas Shaft: LS)

Construction activities could potentially temporarily suspend the normal function of roadways and increase traffic safety hazards near the project sites, due to the frequency and duration of construction related traffic on local roads. Conflicts could occur between construction vehicles (with slower speeds and wider turning radii than autos) and vehicles, bicyclists, or pedestrians using the roadways. Such conflicts could occur within the community of Chrisman on West Vernalis Road where construction related trips for the Tesla Portal site would be concentrated. The risk of conflicts would increase on the four days when concrete delivery trips would be scheduled to occur because of the number of trips and the type of vehicles involved.

Project-related construction activities and construction related traffic could increase the potential for conflicts and safety hazards. However, construction activities at the Tesla Portal and Thomas Shaft project sites would be confined within SFPUC's property, and would not result in lane closures or affect other public rights-of-way (e.g., sidewalks or walkways), and therefore, would limit the potential for conflict between construction traffic and other vehicles, bicyclists and pedestrians on public roadways. In addition, as part of the project, SFPUC Construction Measure #5 (traffic control plan) would be implemented. Therefore, the project impacts at both sites would be less than significant.

Operational Impacts

Impact 4.8-4: Increase in vehicle trips to and from the facility sites for operation and maintenance (Tesla Portal: LS; Thomas Shaft: LS)

Tesla Portal Site

Implementation of the proposed project would result in approximately two new round-trips per day (four daily trips) to and from the Tesla Portal site, generated by the addition of two new full time equivalent (FTE) employees. Generally, FTE trips would be peak hour trips. In addition to

trips generated by new employees, the project would also result in new trips for maintenance, operation and deliveries at the Tesla Portal site. These trips would generate an average of five new round trips per day. At most, the proposed project would generate seven additional round-trips per day (two FTE and five maintenance, operation and delivery related round trips).

Current daily trips at the Tesla Portal site include approximately three daily round-trips (six trips) generated by the three FTEs employed at the site, and 3 daily round-trips for maintenance, operations and delivery related visits. Upon completion of the proposed project at the Tesla Portal site, the facility would generate an average of 13 round trips per day (refer to Table 4.8-3).

TABLE 4.8-3
TESLA PORTAL SITE EXISTING AND PROJECT RELATED TRIPS

Type of Trips	Number of Existing Round-Trips	Number of New Round-Trips	Total Round-Trips	Frequency
Employee Related Trips	3	2	5	Daily
Maintenance, Operation and Delivery Related Trips	3	5	8	Daily
Total:	6	7	13	--

Thomas Shaft Site

The Thomas Shaft site would remain unmanned. However, the facility would continue to receive deliveries of food grade acid once a month and would be visited daily by an operations representative as part of the site's ongoing maintenance (refer to Table 4.8-4).

TABLE 4.8-4
THOMAS SHAFT SITE EXISTING AND PROJECT RELATED TRIPS

Type of Trips	Number of Existing Round-Trips	Number of New Round-Trips	Total Round-Trips	Frequency
Delivery Related Trips	1	0	1	Monthly
Maintenance and Operation Related Trips	1-2	0	1-2	Daily

Given that the main access routes to the project sites (Tesla Portal and Thomas Shaft) operate below their designed traffic volume capacity, the addition of a minimal amount of new project related trips (operations, maintenance and deliveries) at the Tesla Portal project site would not result in a noticeable increase in traffic on adjacent streets even during peak traffic periods. Furthermore, the proposed project would not result in new trips at the Thomas Shaft site. The anticipated new project related trips at the Tesla Portal project site would not generate enough traffic volume to affect LOS standards within the sites' regional roadway systems. Impacts would be less than significant.

4.9 Air Quality

4.9.1 Air Pollutant Properties, Effects, and Sources

Air quality conditions in the vicinity of the Tesla Portal and Thomas Shaft sites are indicated by criteria air pollutants, and are discussed below.

General criteria pollutants include carbon monoxide (CO), particulate matter (PM), nitrogen dioxide (NO_2), ozone (O_3), and sulfur dioxide (SO_2). The measured local concentrations, health effects, and other characteristics of these criteria pollutants are summarized below; green house gas (GHG) emissions, reactive organic gasses (ROG), and volatile organic compounds (VOC) are also addressed, as they are pollutants of concern. Hydrogen sulfide, lead, sulfates, vinyl chloride, and visibility-reducing particles are of least concern in this study area because recorded levels are well below standards; further discussion of these pollutants is not presented. A more detailed description of the local air quality and monitoring stations (including justification for selection) of the study area is provided in Section 4.9.2.

Ozone (O_3)

Ozone (O_3) occurs in two layers of the atmosphere. The layer surrounding the earth's surface is the troposphere. Here, ground level or "harmful" ozone is an air pollutant that has a pungent odor, causes eye irritation, reduces visibility, and damages human health, vegetable crops, and many common materials. The troposphere extends to a level about 10 miles above the earth's surface, where it meets the second layer, called the stratosphere. The stratospheric or "helpful" ozone layer extends upward from about 10 to 30 miles and protects life on earth from the sun's harmful ultraviolet rays.

Unlike other pollutants, ground level ozone is not emitted directly into the air by specific sources. A primary constituent of smog, ozone is formed in the atmosphere in the presence of sunlight by a series of chemical reactions primarily (from a regulatory standpoint) involving oxides of nitrogen (NO_X) and reactive organic gasses (ROG). Because these reactions occur on a regional scale over a period of hours, ozone is considered a regional air pollutant. Industrial fuel combustion and motor vehicles are primary sources of NO_X. Primary sources of ROG are fugitive emissions from petroleum production and commercial use, and solvent evaporation and a wide variety of manufacturing processes.

As shown in Table 4.9-2, ozone concentrations have exceeded the National Ambient Air Quality Standards (NAAQS) and California Ambient Air Quality Standards (CAAQS) at the Stockton-Hazelton Street monitoring station for the past three years (refer to Section 4.9.2 for a discussion of applicable monitoring stations in the project area). These violations, together with other violations throughout the area, have resulted in the study area being designated as nonattainment with respect to the NAAQS and CAAQS for ozone.

Carbon Monoxide (CO)

CO is an odorless, colorless gas that can impair the transport of oxygen in the bloodstream; aggravate cardiovascular disease; and cause fatigue, headache, confusion, and dizziness. CO forms through incomplete combustion of fuels in vehicles, wood stoves, industrial operations, and fireplaces. In San Joaquin County, vehicular exhaust is a major source of CO. CO tends to dissipate rapidly into the atmosphere and consequently is generally a concern at the local level, particularly at major road intersections.

CO concentrations at the Stockton-Hazelton Street monitoring station have been well below the NAAQS and the CAAQS. In fact, all of San Joaquin County is in attainment of the CO standards.

Particulate Matter (PM_{10} and $PM_{2.5}$)

PM is generally composed of particles in the air such as dust, soot, aerosols, fumes, and mists. Of particular concern is PM_{10} (particulates that have aerodynamic diameters of 10 micrometers or less). A subgroup of PM_{10} is $PM_{2.5}$ (particles with aerodynamic diameters less than 2.5 micrometers), which have very different characteristics, sources, and potential health effects than particles with an aerodynamic diameter between 2.5 to 10 micrometers.

PM_{10} is generated by sources such as windblown dust, agricultural fields, and dust from vehicular traffic on unpaved roads. $PM_{2.5}$ is generally emitted from activities such as industrial combustion, vehicle exhaust, and residential wood-burning stoves and fireplaces. $PM_{2.5}$ is also formed in the atmosphere when gases such as SO_2, NO_X, and ROG are transformed by chemical reactions in the atmosphere. PM_{10} affects breathing and the respiratory system, and, in particular, can damage lung tissue, and contribute to cancer and premature death.

Separate standards for $PM_{2.5}$ were established in 1997 because these smaller particles can penetrate deep into the respiratory tract and cause adverse health effects even when the PM_{10} levels are below the 1997 PM_{10} standards (U.S. EPA, 1997). Health studies have shown a significant association between exposure to $PM_{2.5}$ and premature mortality. Other important effects include aggravation of respiratory and cardiovascular disease (as indicated by increased hospital admissions, emergency room visits, absences from school or work, and restricted activity days), lung disease, decreased lung function, asthma attacks, and certain cardiovascular problems such as heart attacks and cardiac arrhythmia. Individuals particularly sensitive to $PM_{2.5}$ exposure include older adults, people with heart and lung disease, and children.

Measured concentrations at the Stockton-Hazelton Street monitoring station (Table 4.9-2) have exceeded the CAAQS for the past three years and show one violation of the NAAQS in 2005. These violations, together with other violations throughout the area, have resulted in the study area being designated as nonattainment with respect to the NAAQS and CAAQS for PM_{10} and $PM_{2.5}$.

Nitrogen Dioxide (NO_2)

NO_2 is a brownish, highly reactive gas that can irritate the lungs, cause pneumonia, and lower resistance to respiratory infections. NO_X, which includes NO_2, is a key precursor to O_3 and acid

rain. NO_X forms when fuel is burned at high temperatures, principally from transportation sources and stationary fuel combustion sources such as electric utility and industrial boilers.

Table 4.9-2 shows that measured concentrations of NO_2 have consistently remained below the NAAQS and CAAQS standards for NO_2. In fact, all of San Joaquin County is in attainment of the NO_2 standards.

Reactive Organic Gases (ROG) and Volatile Organic Compounds (VOC) – Precursors to Ozone

Hydrocarbons are organic gases that are formed solely of hydrogen and carbon. There are several subsets of organic gases, including VOCs and ROGs. ROGs include all hydrocarbons except those exempted by California Air Resources Board (CARB). Therefore, ROGs are a set of organic gases based on state rules and regulations. VOCs are similar to ROGs in that they include all organic gases except those exempted by federal law. Both VOCs and ROGs are emitted from incomplete combustion of hydrocarbons or other carbon-based fuels. Combustion engine exhaust from automobiles and trucks and oil refineries are the primary sources of hydrocarbons. Another source of hydrocarbons is evaporation from petroleum fuels, solvents, dry cleaning solutions, and paint.

The primary health effects of hydrocarbons result from the formation of ozone and its related health effects (see ozone health effects discussion above). High levels of hydrocarbons in the atmosphere can interfere with oxygen intake by reducing the amount of available oxygen through displacement. There are no separate NAAQS or CAAQS for ROGs. Carcinogenic forms of ROGs are considered toxic air contaminants (TACs) and are discussed briefly below.

Sulfur Dioxide (SO_2)

SO_2 is a colorless acidic gas with a strong odor at high concentration levels. High concentrations of SO_2 affect breathing and may aggravate existing respiratory and cardiovascular disease. SO_2 is also a primary contributor to acid deposition, which causes acidification of lakes and streams and can damage trees, crops, building materials, and statues. In addition, sulfur compounds in the air can contribute to visibility impairment. The major source category for SO_2 is fuel-burning equipment combusting fossil fuels.

SO_2 has not been measured at the Stockton-Hazelton Street monitoring station for the past three years. This is not problematic, as the area has been designated as attainment for the NAAQS and CAAQS for SO_2. Other stations throughout the San Joaquin Valley Air Basin (SJVAB) have measured concentrations well within NAAQS and CAAQS for SO_2.

Greenhouse Gases

The earth's atmosphere naturally contains a number of gases, including (but not limited to) carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O), which are collectively referred to as greenhouse gases (GHG). GHG emissions are generally numerically depicted (when applicable) as carbon dioxide equivalents (CO_2e). CO_2e represents CO_2 plus the additional warming potential from CH_4 and N_2O. In general, CH_4 and N_2O have 21 and 310 times the

warming potential of CO_2, respectively. Manmade emissions of GHG occur through the combustion of fuels, as well as a variety of other sources.

These gases trap some amount of solar radiation and the earth's own radiation, preventing it from passing through earth's atmosphere and into space. GHG are vital to life on earth; without them, earth would be an icy planet. For example, CO_2 is an element that is essential to the cycle of life. However, increasing GHG concentrations are believed to be warming the planet.

As the average temperature of the earth increases, weather may be affected, including changes in precipitation patterns, accumulation of snow pack, and intensity and duration of spring snowmelt. The sea level may rise, resulting in coastal erosion and inundation of coastal areas. Emissions of air pollutants and ambient levels of pollutants also may be affected in areas. Climate zones may change, affecting the ecology and biological resources of a region. There may be changes in fire hazards due to the changes in precipitation and climate zones.

While scientists have established a connection between increasing GHG concentrations and increasing average temperatures, important scientific questions remain about how much warming would occur, how fast it would occur, and how the warming would affect the rest of the climate system. At this point, scientific efforts are unable to quantify the degree to which human activity impacts climate change. The phenomenon is worldwide, yet it is expected that there would be substantial regional and local variability in climate changes. It is not possible with today's science to determine the effects of global climate change in a specific locale, or whether the effect of one aspect of climate change may be counteracted by another aspect of climate change, or exacerbated by it.

Human activities generate GHG. Since pre-industrial times, there has been a buildup of levels of GHG in the atmosphere. The human contribution to the increase in atmospheric GHG concentrations largely has resulted from the burning of fossil fuels. Fossil fuel combustion accounts for approximately 98 percent of GHG emissions from human activity.

GHG emissions in California are less than the national average, both in per capita emissions and in emissions per gross state product. Transportation is the largest source of CO_2e emissions in California, accounting for approximately 37 percent of total emissions. Electricity generation accounts for approximately 34 percent of CO_2e emissions in California, and the industrial sector accounts for approximately 6 percent (CARB, 2007b).

Toxic Air Contaminants (TAC)

In addition to the criteria pollutants discussed above, TACs are another group of pollutants of concern. There are many different types of TACs, with varying degrees of toxicity. Sources of TACs include industrial processes such as petroleum refining and chrome-plating operations, commercial operations such as gasoline stations and dry cleaners, and motor vehicle exhaust. Cars and trucks release at least 40 different toxic air contaminants. The most important, in terms of health risk, are diesel particulate, benzene, formaldehyde, 1,3-butadiene, and acetaldehyde. Public exposure to TACs can result from emissions from normal operations as well as accidental releases. Health effects of TACs include cancer, birth defects, neurological damage, and death.

4.9.2 Setting

As described in the project description (Chapter 3.0), the project is comprised of modifications at two separate sites: the Tesla Portal site and the Thomas Shaft site. Both project sites are within the SJVAB. The climate and topography of this air basin are discussed below. The SJVAB includes the counties of San Joaquin, Stanislaus, Merced, Madera, Fresno, Kings, Tulare, and a portion of Kern County.

San Joaquin Valley Air Basin

A horseshoe-shaped rim of mountains formed primarily by the Sierra Madre, Tehachapi, and Sierra Nevada mountain ranges surrounds the SJVAB. The Sierra Nevada Mountains to the northeast block most of the cold air that flows southward over the continent during the winter months. They also catch and store snow, providing irrigation water for use during the dry months. The Tehachapi Mountains, which form the southern boundary, obstruct winds from the northwest, causing heavier precipitation on the windward slopes, high wind velocity over the ridges, and occasional cloudiness in the south end of the valley that continues after skies have cleared elsewhere. The coastal ranges form the SJVAB western boundary, and the Pacific Ocean shore lies at a distance of 75 to 100 miles to the west.

The SJVAB has an "inland Mediterranean" climate, which is characterized by hot, dry summers and cool, rainy winters. The semi-permanent "Pacific High" over the eastern Pacific Ocean dominates the weather during the summer months, blocking low-pressure systems from passing through the area. Summers are cloudless, hot, and dry, with a normal daily maximum temperature of 98 degrees Fahrenheit (°F) in July. Severe freezes seldom occur and there are occasional years with no frost in certain warm areas. Winters are mild and semi-arid, yet fairly humid. December and January are characterized by frequent fog, mostly nocturnal, which prevails when marine air is trapped in the valley by high-pressure systems. The average daily minimum temperature in December is 56°F.

Precipitation in the SJVAB is confined primarily to the winter months, with some occurring in late fall and early spring. Nearly 90 percent of the annual precipitation in the SJVAB falls between the months of November and April. The amount of rainfall in the SJVAB varies by region, with the greatest amount occurring in the northern and eastern parts of the basin. The average annual rainfall in the SJVAB is about 10 inches.

Wind speed and direction data indicate that wind patterns tend to be seasonal. During the summer, light and variable winds usually result from an influx of air from the Pacific Ocean through the Bay Area delta region, entering the north end of the valley. The wind generally flows in a south-southeasterly direction through the valley, through the Tehachapi Pass, and into the Southeast Desert Air Basin portion of Kern County. In winter months, occasional south-southeasterly winds flow across the valley, and the valley experiences light, variable winds of less than 10 miles per hour.

A meteorological phenomenon known as inversion layer formation occurs in the SJVAB. Inversion layers are formed when the air temperature increases with elevation above the ground, as opposed to the normal decrease in temperature with height. This effect reduces the amount of

vertical mixing that occurs above the ground and can lead to pollution such as smog being trapped in higher concentrations close to the ground, with possible adverse effects on health. Inversion layer formation in the SJVAB is caused by nocturnal cooling of air near the ground surface, or by downward vertical motion in the atmosphere. Inversion layers are more stable during the winter months, when inversions occur from 50 to 1,000 feet above the SJVAB floor.

Ambient Air Quality

The federal government and the state government of California have established separate ambient air quality standards. The U.S. Environmental Protection Agency (U.S. EPA) has established primary and secondary National Ambient Air Quality Standards (NAAQS) that specify allowable ambient concentrations for criteria pollutants under the provisions of the Clean Air Act. Primary NAAQS are established at levels necessary, with an adequate margin of safety, to protect the public health, including the health of sensitive populations such as asthmatics, children, and the elderly. Similarly, secondary NAAQS specify the allowable levels of air quality determined appropriate to protect the public welfare from any known or anticipated adverse effects associated with air contaminants. NAAQS are set for carbon monoxide (CO), lead (Pb), respirable particular matter (PM_{10}), fine particulate matter ($PM_{2.5}$), nitrogen dioxide (NO_2), ozone, and sulfur dioxide (SO_2).

Table 4.9-1 summarizes the NAAQS for these pollutants. The 8-hour ozone and $PM_{2.5}$ standards listed in the table were promulgated in 1997 but were challenged in the courts. In 2002, the courts upheld these two standards. The U.S. EPA made final designations for the 8-hour ozone standards on April 15, 2004, and made final designations for the new federal $PM_{2.5}$ standards on December 2004. Recently, the U.S. EPA approved a more stringent 8-hour ozone standard (2008) and a more stringent $PM_{2.5}$ standard (2006). U.S. EPA and the states are currently working together to develop air quality plans to achieve compliance with these standards, where needed.

In California, the California Air Resources Board (CARB), which is part of the California Environmental Protection Agency, has promulgated California Ambient Air Quality Standards (CAAQS) for CO, Pb, PM_{10}, $PM_{2.5}$, NO_2, ozone, and SO_2 that are more stringent than U.S. EPA's NAAQS, as shown in Table 4.9-1. In 2002, CARB revised the state annual PM_{10} standard and established an annual $PM_{2.5}$ standard. These standards went into effect July 7, 2004. In April 2005, CARB approved a new 8-hour average standard for ozone that went into effect on May 17, 2006. CARB has also developed standards for hydrogen sulfide, sulfates, vinyl chloride, and visibility-reducing particles.

Areas (portions of or entire air districts, counties, or air basins) in California are classified separately as being either in attainment or nonattainment of the NAAQS and the CAAQS. An area's classification is determined by comparing actual monitored air pollutant concentrations to the NAAQS and the CAAQS. More than 200 air monitoring stations are located throughout California and are part of the State and Local Air Monitoring Network. These stations are operated by CARB, local Air Pollution Control Districts (APCDs) or Air Quality Management Districts (AQMDs), private contractors, and the National Park Service (NPS). Areas that do not have sufficient data for an attainment/nonattainment determination are given an unclassified designation and are not considered to be nonattainment.

TABLE 4.9-1

FEDERAL AND CALIFORNIA AMBIENT AIR QUALITY STANDARDS

Pollutant	Averaging Time	NAAQS [1]	CAAQS
CO	1-Hour	35 ppm	20 ppm
	8-Hour	9 ppm	9.0 ppm
	8-Hour (Lake Tahoe)	None	6 ppm
NO_2	1-Hour	None	0.18 ppm
	Annual Average	0.053 ppm	0.030 ppm
Ozone	1-Hour	None [2]	0.09 ppm
	8-Hour	0.08 ppm (1997) 0.075 ppm (2008) [3]	0.070 ppm
Pb	30 days	None	1.5 $\mu g/m^3$
	Calendar Quarter	1.5 $\mu g/m^3$	None
PM_{10}	24-Hour	150 $\mu g/m^3$	50 $\mu g/m^3$
	Annual Average	Revoked [4]	20 $\mu g/m^3$
$PM_{2.5}$	24-Hour	65 $\mu g/m^3$ (1997) 35 $\mu g/m^3$ (2006) [5]	None
	Annual Average	15 $\mu g/m^3$	12 $\mu g/m^3$
SO_2	1-Hour	None	0.25 ppm
	3-Hour	0.5 ppm [6]	None
	24-Hour	0.14 ppm	0.04 ppm
	Annual Average	0.03 ppm	None
Hydrogen Sulfide	1-Hour		0.03 ppm
Sulfates	24-Hour	No Federal Standards	25 $\mu g/m^3$
Vinyl Chloride	24-Hour		0.01 ppm
Visibility Reducing Particles	8-Hour		Extinction coefficient of 0.23 per kilometer

Source: CARB, 2008a and U.S. EPA, 2008a

1 Primary NAAQS unless otherwise noted.

2 1-hour ozone standard revoked June 5, 2005, except for areas that do not yet have an effective date for their 8-hour designations.

3 "The 1997 standard—and the implementation rules for that standard—will remain in place for implementation purposes as EPA undertakes rulemaking to address the transition from the 1997 ozone standard to the 2008 ozone standard." (U.S. EPA, 2008a)

4 Due to a lack of evidence linking health problems to long-term exposure to coarse particle pollution, EPA revoked the annual PM_{10} standard in 2006 (effective December 17, 2006).

5 The 35 micrograms per cubic meter of air standard became effective December 17, 2006. The new standard will be applicable to measurements beginning with year 2007; 65 micrograms per cubic meter of air prior to 2007.

6 Secondary NAAQS.

The ambient pollutant monitoring stations closest to the project area are located in cities of Tracy, and Stockton. The City of Tracy has two monitoring stations:

- Tracy – 24371 Patterson Pass Road Station – This site only monitors only ozone (both 1-hour and 8-hour) and NO_2. There are no measurements for 2005 or 2006.

- Tracy – Airport Station – This site only monitors only ozone (both 1-hr and 8-hr) and NO_2. There are no measurements for 2004 or 2005.

The City of Stockton has two monitoring stations:

- Stockton – Wagner-Holt School – This site only monitors only PM_{10}.

- Stockton-Hazelton Street – This site monitors all criteria pollutants except for SO_2. Data are also available from 2004 – 2006.

Due to the availability of data, pollutant concentrations from the Stockton-Hazelton Street Station will be summarized to depict the local air quality, despite the fact that the Tracy monitoring stations are closer to the project area. Table 4.9-2 summarizes the measured criteria pollutant concentrations over the past three years (2004 – 2006) at the Stockton-Hazelton Street Station. SO_2 is not monitored at this station. However, this is not problematic, as the area is designated as unclassified/attainment of the SO_2 NAAQS and CAAQS.

At the Stockton-Hazelton Street monitoring station (Table 4.9-2), measured ozone concentrations have exceeded the NAAQS and the CAAQS; measured PM_{10} concentrations have exceeded the CAAQS; and measured $PM_{2.5}$ concentrations have exceeded the NAAQS and CAAQS. Formal attainment designations, however, are based on all monitored levels throughout the designated area (which varies and can mean portions of or entire air districts, counties, or air basins). As such, the study area is designated as:

- Serious nonattainment of the 8-hour ozone NAAQS and nonattainment of the 1-hour and 8-hour ozone CAAQS;

- Serious nonattainment of the 24-hour PM_{10} NAAQS (this is the current designation; re-designation of the NAAQS has been requested, as detailed in Section 4.9.2.1) and nonattainment of the 24-hour and annual PM_{10} CAAQS; and

- Nonattainment of the 24-hour and annual $PM_{2.5}$ NAAQS and nonattainment of the annual $PM_{2.5}$ CAAQS.

TABLE 4.9-2

Notes:

Federal/state values. The federal and state values can differ due to differences in sampling methods and criteria. Federal and state values are provided separately. Federal values are generally taken from U.S. EPA data; State values are taken from CARB data.

$\mu g/m^3$ = micrograms per cubic meter; NA= not available; ppm = parts per million

Existing Emissions Sources

The concentrations of the criteria pollutants presented above are a result of emissions from man-made and natural sources. Manmade sources of emissions are generally divided into three types: stationary, area-wide, and mobile. The contributions of these source categories vary from region to region. CARB maintains an emissions inventory to determine the sources and quantities of air pollution generated within the state's counties and air basins. Table 4.9-3 presents a summary of the projected 2006 pollutant emission data for San Joaquin County.

The Tesla Portal and Thomas shaft sites both contribute minimally to the existing air quality totals listed in 4.9-3. The Tesla Portal and Thomas Shaft sites both contribute to mobile source emissions due to the use of employee, maintenance, and equipment delivery vehicles. Both sites contribute to stationary source emissions due to the use of back-up generators.

Sensitive Receptors

According to the San Joaquin Guide to Assessing and Mitigating Air Quality Impacts (GAMAQI), "for CEQA purposes, a sensitive receptor is generically defined as a location where human populations, especially children, seniors, and sick persons are found, and there is reasonable expectation of continuous human exposure according to the averaging period for the AAQS (e.g., 24-hour, 8-hour, 1-hour)" (SJVAPCD, 2002). Sensitive receptors typically include residences, hospitals, schools, and parks.

There are no sensitive receptors in the immediate vicinity of the project sites. The residential structure closest to the Tesla Portal site is approximately 2,500 feet to the southeast of the project area, off West Vernalis Road. Roughly 0.5 mile to the east lies the community of Chrisman, which is an unincorporated rural residential area within the Tracy Planning Area and consists of

approximately 36 rural residential parcels. Aerial photographs show the nearest rural residence about 1.25 miles to the northeast of the Thomas Shaft site.

4.9.3 Regulatory Framework

This section provides information relating to adopted federal, state, and local regulations and policies that govern air quality in the project vicinity and are applicable to the projects emissions.

Air quality in the project vicinity is regulated by several agencies, including the U.S. EPA, the CARB, and the San Joaquin Valley Air Pollution Control District (SJVAPCD). Although U.S. EPA regulations may not be superseded, both state and local regulations may be more stringent than the federal requirements. The U.S. EPA is responsible for establishing the NAAQS, setting minimum New Source Review permitting and Operating Permit requirements for stationary sources; establishing New Source Performance Standards, National Emission Standards for Hazardous Pollutants and the Acid Deposition Control program; and administering regional air quality initiatives. The CARB's role includes development, implementation, and enforcement of California's motor vehicle pollution control program; administration of the state's air pollution research program; adoption and updating, as necessary, of CAAQS; review of local APCD activities, and coordination of the development of the State Implementation Plan (SIP) for achievement of the NAAQS. Local APCDs are responsible for implementing federal and state regulations at the local level, permitting stationary sources of air pollution, and developing the local elements of the SIP. Emissions from indirect sources, such as automobile traffic associated with development projects, are addressed through the APCD's air quality plans.

The project sites are located in San Joaquin County, which is located within the northernmost portion of the SJVAB and is under the jurisdiction of the SJVAPCD. The following three subsections describe in more detail the roles and requirements at the federal, state, and local levels of government. In addition to this, a fourth section including a review of recent federal and state regulations that cover GHGs is provided.

Federal

The federal government, through the U.S. EPA, has established primary and secondary NAAQS for criteria pollutants under the provisions of the Clean Air Act (see Table 4.9-1). The U.S. EPA has classified air basins (or portions thereof) as being in "attainment" or "nonattainment" or "unclassified" for each criteria air pollutant. An area is designated as being in attainment of a standard if the pollutant concentrations are consistently below the NAAQS, and it is classified as being in nonattainment if pollutant concentrations exceed the NAAQS. An area may be unclassified if insufficient air quality data are available on which to base a nonattainment or attainment designation.

The project sites are in the SJVAPCD, which is a nonattainment area for the federal 8-hour O_3, PM_{10}, and $PM_{2.5}$ NAAQS. For areas classified as being in nonattainment, the federal Clean Air Act requires states to develop and adopt a SIP, an air quality plan showing how air quality

standards will be attained/maintained. In California, the U.S. EPA has delegated SIP preparation to CARB, which, in turn, has delegated that authority to the individual APCDs.

To satisfy U.S. EPA state implementation requirements, CARB, with the help of the SJVAPCD, has compiled the following plans (most recent updates shown):

- San Joaquin Valley's 2007 Ozone Plan. The plan sets out the strategy to attain the federal 8-hour ozone standard by 2024. In September, the ARB strengthened the State's commitments to reduce emissions in the Valley in advance of the 2024 attainment date. (CARB, 2008d)

- San Joaquin Valley Unified Air Pollution Control District's (District) 2007 PM_{10} Maintenance Plan and Request for Redesignation (2007 Maintenance Plan) with modifications to the transportation conformity budgets. (CARB, 2008d)

- San Joaquin Unified Air Pollution Control District's (District) 2008 $PM_{2.5}$ Plan. (CARB, 2008d)

The federal Clean Air Act also regulates hazardous air pollutants (HAPs), airborne pollutants that are known to have adverse human health effects. Unlike criteria pollutants, HAPs do not have adopted ambient air quality standards. HAPs have been regulated at the federal level since the Clean Air Act of 1977 under Title 40 of the Code of Federal Regulations, Part 61 (40 CFR Part 61). The proposed project is not considered to be a major source of HAPs. A source that emits more than 10 tons per year of any single HAP or 25 tons per year of all combined HAPs would be considered a major source of HAPs.

State

In California, the lead air quality agency is the CARB. The CARB has promulgated CAAQS for O_3, PM_{10}, $PM_{2.5}$, CO, NO_2, SO_2, and Pb that are more stringent than the U.S. EPA's standards, as shown in Table 4.9-1. As with the federal ambient air standards, air basin areas (or portions thereof) are classified as being in attainment or nonattainment with respect to the CAAQS. The California Clean Air Act requires that each air basin area exceeding the CAAQS for O_3, CO, SO_2, PM_{10}, $PM_{2.5}$, or NO_2 must develop a plan aimed at achieving those standards in accordance with California Health and Safety Code 40911. The California Health and Safety Code Section 40914 requires each air district that is in nonattainment to design a plan that will achieve an annual reduction in district-wide emissions of 5 percent or more, averaged every consecutive three-year period. As previously discussed, the project sites are located in the SJVAPCD, which is a nonattainment area for the O_3, PM_{10}, and $PM_{2.5}$ CAAQS. As such, CARB has developed several implementation plans, as discussed in Section 4.9.2.1.

California also regulates TACs, which is a class of airborne pollutants similar to the federal HAPs. California's air toxics control program began in 1983 with the passage of the Toxic Air Contaminant Identification and Control Act, better known as Assembly Bill 1807 (AB 1807) or the Tanner Bill. The Tanner Bill established a regulatory process for the scientific and public

review of individual toxic compounds. When a compound becomes listed as a TAC under the Tanner process, CARB normally establishes minimum statewide emission control measures to be adopted by local APCD. By 1992, 18 of the 189 federal HAPs had been listed by CARB as state TACs. Later legislative amendments (AB 2728, Tanner 1992) required CARB to incorporate all 189 federal HAPs into the state list of TACs.

The second major component of California's air toxics program, which supplements the Tanner process, was provided by the passage of AB 2588, the Air Toxics "Hot Spots" Information and Assessment Act of 1987. AB 2588 currently regulates over 600 air compounds, including all of the Tanner-designated TACs. Under AB 2588, specified facilities must quantify emissions of regulated air toxics and report them to the local APCD or AQMD. If the APCD determines that a potentially significant public health risk is posed by a given facility, the facility is required to perform a health risk assessment and notify the public in the effected area if the calculated risks exceed specified criteria.

On August 27, 1998, CARB formally identified particulate matter emitted by diesel-fueled engines as a TAC. Diesel engines emit TACs in both gaseous and particulate forms. The particles emitted by diesel engines are coated with chemicals, many of which have been identified as HAPs by the U.S. EPA, and as TACs by CARB. Since by weight, the vast majority of diesel exhaust particles are very small (94 percent of their combined mass consists of particles less than 2.5 microns in diameter), both the particles and their coating of TACs are inhaled into the lungs. While the gaseous portion of diesel exhaust also contains other TACs, CARB's August 1998 action was specific to diesel particulate matter (DPM) emissions, which, according to supporting CARB studies, represent 50 to 90 percent of the mutagenicity (ability to cause mutations that lead to cancer) of diesel exhaust. Accordingly, diesel particulates are generally used as a surrogate to identify potential health risks from diesel emissions (CARB, 1998, 2006).

CARB's 1998 ruling prompted CARB to begin searching for means to reduce DPM emissions. In September 2000, CARB approved the Risk Reduction Plan to Reduce Particulate Matter Emissions from Diesel-Fueled Engines and Vehicles. The Diesel Risk Reduction Plan outlines a comprehensive and ambitious program that includes the development of numerous new control measures over the next several years aimed at substantially reducing emissions from new and existing on-road vehicles (e.g., heavy-duty trucks and buses), off-road equipment (e.g., graders, tractors, forklifts, sweepers, and boats), portable equipment (e.g., pumps), and stationary engines (e.g., stand-by power generators).

Local

At the local level, the SJVAPCD regulates air quality by establishing local air quality regulations, permitting stationary sources, and planning activities related to air quality. The District is also responsible for enforcing and implementing all NAAQS and CAAQS. In areas that are in nonattainment of a federal standard, the local district assists CARB in the development of the SIP. Current plans are discussed in Section 4.9.2.1.

The SJVAPCD has developed significance thresholds for operational air pollutant emissions. Projects with the potential to generate operational emissions exceeding those thresholds would be considered to have a significant impact on air quality and would require appropriate mitigation measures.

The SJVAPCD published the GAMAQI in 2002, which "is an advisory document that provides Lead Agencies, consultants, and project applicants with uniform procedures for addressing air quality in environmental documents" (SJVAPCD, 2002). In practice, the GAMAQI provides details regarding significance thresholds, mitigation measures, and guidance for evaluating air quality impacts under the CEQA process.

The SJVAPCD operational emission thresholds are summarized in Table 4.9-4. Feasible mitigation measures must be applied to reduce operational emissions below the significance thresholds during operation of any project within the SJVAPCD. If emissions cannot be reduced below the thresholds, then emissions are considered to have a significant impact on air quality.

TABLE 4.9-4
SUMMARY OF OPERATIONAL SIGNIFICANCE THRESHOLDS FOR SJVAPCD

Air Pollutant	SJVAPCD (tons/year)
ROG	10
NO_X	10

Notes:
NO_X = nitrogen dioxide
ROG = reactive organic gases
SJVAPCD = San Joaquin Valley Air Pollution Control District

In accordance with the GAMAQI, construction emissions are considered less than significant if the project adheres to the control measures required in the GAMAQI. No formal numerical thresholds are developed for construction emissions (SJVAPCD, 2002).

Greenhouse Gas Emissions

In 1988, the United Nations established the Intergovernmental Panel on Climate Change to evaluate the impacts of global warming and to develop strategies that nations could implement to curtail global climate change. In 1992, the United Nations Framework Convention on Climate Change established an agreement with the goal of controlling GHG emissions, including CH_4.

As a result, the Climate Change Action Plan was developed to address the reduction of GHG in the United States. The plan consists of more than 50 voluntary programs.

Currently, the U.S. EPA does not regulate GHG emissions. In *Massachusetts v. U.S. EPA*, decided April 2, 2007, the U.S. Supreme Court held that U.S. EPA has the authority to regulate GHG emissions from cars and trucks under the Clean Air Act. However, the court did not decide whether U.S. EPA is required to regulate GHG emissions, or may exercise discretion to not

regulate at this time. Currently, U.S. EPA has not adopted any regulations to date directly regulating emissions of GHG.

The federal government recently passed the Energy Independence and Security Act of 2007, which mandates a host of actions that would aid in the reduction of GHGs. However, the federal government has stopped short of directly regulating GHG emissions. These new actions include (but are not limited to): fuel economy standard of 35 miles per gallon by 2020; improve energy efficiency in lighting and appliances; and investments in efficiency and renewable energy use (White House, 2008).

In 2005, Governor Schwarzenegger established Executive Order S-3-05, which sets forth a series of target dates by which statewide emissions of GHG would be progressively reduced, as follows:

- By 2010, reduce GHG emissions to 2000 levels;
- By 2020, reduce GHG emissions to 1990 levels; and
- By 2050, reduce GHG emissions to 80 percent below 1990 levels.

In 2006, California passed the California Global Warming Solutions Act of 2006 (Assembly Bill No. 32; California Health and Safety Code Division 25.5, Sections 38500, et seq., or AB 32), which requires the CARB to design and implement emission limits, regulations, and other measures, such that feasible and cost-effective statewide GHG emissions are reduced to 1990 levels by 2020 (representing a 25 percent reduction in emissions).

The Act defines GHG emissions as all of the following gases: CO_2, CH_4, N_2O, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride. This agreement represents the first enforceable statewide program in the United States to cap all GHG emissions from major industries that includes penalties for noncompliance. While acknowledging that national and international actions will be necessary to fully address the issue of global warming, AB 32 lays out a program to inventory and reduce GHG emissions in California and from power generation facilities located outside the state that serve California residents and businesses.

AB 32 established a timetable for the CARB to adopt emission limits, rules, and regulations designed to achieve the intent of the Act, as follows (AB 32):

- Publish a list of discrete early action GHG emission reduction measures by June 30, 2007.
- Establish a statewide GHG emissions cap for 2020, equivalent to the 1990 emissions level by January 1, 2008.
- Adopt mandatory reporting rules for significant sources of GHGs by January 1, 2008.

- Adopt a scoping plan by January 1, 2009, indicating how GHG emission reductions will be achieved from significant GHG sources via regulations, market-based compliance mechanisms and other actions, including the recommendation of a de minimis threshold for GHG emissions, below which emission reduction requirements would not apply.

- Adopt regulations by January 1, 2011 to achieve the maximum technologically feasible and cost-effective reductions in GHGs, including provisions for using both market-based and alternative compliance mechanisms.

- Establish January 1, 2012 as the date by which all regulations adopted prior to January 1, 2010 are to become operative (enforceable).

As directed by AB 32, CARB has developed a series of "Early Action Measures" to reduce GHG emissions. The intent of these measures is to make a substantial contribution to the overall 2020 statewide GHG emission reduction goal. The early action measures are divided into three groups as follows:

- **Group 1:** Three new GHG-only regulations are proposed to meet the narrow legal definition of "discrete early action GHG reduction measures": a low-carbon fuel standard, reduction of refrigerant losses from motor vehicle air conditioning system maintenance, and increased methane capture from landfills. These regulations are expected to take effect by January 1, 2010.

- **Group 2:** The CARB is initiating work on 23 other GHG emission-reducing measures in the 2007-to-2009 time period with rulemaking to occur as soon as possible, where applicable. These GHG measures relate to the following sectors: agriculture, commercial, education, energy efficiency, fire suppression, forestry, oil and gas, and transportation.

- **Group 3:** The CARB is initiating work on 10 conventional air pollution controls aimed at criteria and toxic air pollutants, but with concurrent climate co-benefits through reductions in carbon dioxide or non-Kyoto pollutants (i.e., diesel particulate matter, other light-absorbing compounds, and/or ozone precursors) that contribute to global warming.

As directed by AB 32, CARB has also approved a statewide greenhouse gas emissions limit. On December 6, 2007, CARB staff resolved an amount of 427 million metric tons of CO_2e as the total statewide greenhouse gas 1990 emissions level and 2020 emissions limit. The limit is a cumulative statewide limit, not a sector or facility specific limit (CARB, 2007a).

On December 6, 2007, the Air Resources Board (ARB) approved a regulation for the mandatory reporting of greenhouse gas emissions from major sources, pursuant to the California Global Warming Solutions Act of 2006. The Board directed ARB staff to make specified changes and appropriate conforming modifications to the proposed regulation that was released on October 19, 2007. The revised regulation was made available for a "15-day" public review and comment

between May 15 and June 5, 2008. Staff is currently reviewing these comments and considering whether further revisions are needed. (CARB, 2008e)

CARB is then to conduct rulemaking, culminating in rule adoption by January 1, 2011, for reducing GHG emissions to achieve the emissions cap by 2020. The rules must take effect no later than 2012. In designing emission reduction measures, CARB must aim to minimize costs, maximize benefits, improve and modernize California's energy infrastructure, maintain electric system reliability, maximize additional environmental and economic co-benefits for California, and complement the state's efforts to improve air quality.

In concurrence with the state's plans for GHG reductions, CEQA documents must address the effect of GHG emissions from new projects. However, the analytical tools required to do so are still being developed. There is currently no established guidance or method to determine the effect on worldwide global warming from a particular increase in GHG emissions, or the resulting effects on climate change in a particular locale. Accordingly, no CEQA significance threshold has yet been developed to evaluate the impacts of the proposed project, or any project, on global climate change or on the environment in California.

The approach used in this report for addressing the significance of GHG is detailed under Impact 4.9-7.

Climate Action Plan for San Francisco

In February 2002, the San Francisco Board of Supervisors passed the Greenhouse Gas Emissions Reduction Resolution (Number 158-02) committing the CCSF to a GHG emissions reduction goal of 20 percent below 1990 levels by the year 2012. The resolution also directs the San Francisco Department of the Environment (SFDE), the SFPUC, and other appropriate City agencies to complete and coordinate an analysis and planning of a local action plan targeting GHG emission-reduction activities. In September 2004, the SFDE and the SFPUC published the *Climate Action Plan for San Francisco: Local Actions to Reduce Greenhouse Emissions* (SFDE and SFPUC, 2004). Although the San Francisco Board of Supervisors has not formally committed the City to perform the actions addressed in the plan, and many of the actions require further development and commitment of resources, it serves as a blueprint for GHG emission reductions, and several actions are now in progress.

The plan presents estimates of San Francisco's baseline GHG inventory and reduction targets. It states that burning fossil fuels in vehicles and for energy use in buildings and facilities are the major contributors to San Francisco's GHG emissions; in 1990, these activities produced approximately 9.1 million tons of CO_2. The plan also recommends emissions reduction actions in the key target sectors (transportation, energy efficiency, renewable energy, and solid waste management) to meet stated goals by 2012.

Greenhouse Gas Reduction Ordinance

In May 2008, San Francisco adopted an ordinance amending its Environment Code to establish greenhouse gas emission targets and action plans, to authorize the Department of the

Environment to coordinate efforts to meet these targets, and to make environmental findings. The ordinance establishes the following greenhouse gas emission reduction limits for San Francisco and the target dates to achieve them:

- Determine 1990 City greenhouse gas emissions by 2008, the baseline level with reference to which target reductions are set;
- Reduce greenhouse gas emissions by 25 percent below 1990 levels by 2017;
- Reduce greenhouse gas emissions by 40 percent below 1990 levels by 2025; and
- Reduce greenhouse gas emissions by 80 percent below 1990 levels by 2050.

The ordinance also specifies requirements for City departments to prepare Climate Action Plans that assess and report GHG emissions and prepare recommendations to reduce emissions. As part of this, the San Francisco Planning Department is required to: (1) update and amend the City's applicable General Plan elements to include the emissions reduction limits set forth in this ordinance and policies to achieve those targets; (2) consider a project's impact on the City's GHG reduction limits specified in this ordinance as part of its review under CEQA; and (3) work with other City departments to enhance the "transit first" policy to encourage a shift to sustainable modes of transportation thereby reducing emissions and helping to achieve the targets set forth by this ordinance.

Existing CCSF GHG Reduction Actions

The CCSF is already implementing a range of actions related to the reduction of GHG emissions. Some of these actions relate to transportation, solar power, and energy efficiency. With regard to transportation, in 1999 the Board adopted the Healthy Air and Smog Prevention Act, which was incorporated into San Francisco's Environment Code. This ordinance requires the CCSF to purchase or lease passenger vehicles and light-duty trucks that are rated as ultra-low-emission vehicles or zero-emission vehicles (ZEV) (at least 10 percent were to be ZEV by July 1, 2000). Requirements were also set forth for medium and heavy-duty vehicles and motorized equipment, and for phasing out all highly polluting vehicles and equipment (SFDE and SFPUC, 2004). The CCSF has also contributed grant funds toward the development of three alternate fueling facilities. It continues to seek funds to expand alternate fueling infrastructure and has been successful in developing a number of electric-vehicle charging stations in San Francisco and throughout the Bay Area. In addition, the CCSF encourages car sharing within San Francisco and limits the amount of parking allowed in new downtown residential developments (Planning Code Section 151.1). The CCSF funds municipal solar and energy-efficiency programs through SFPUC Power Enterprise (formerly part of Hetch Hetchy Water and Power Enterprise) revenues, state grants and loans, and the City's General Fund at approximately $5.5 million annually.

Existing SFPUC GHG Reduction Actions

The SFPUC owns and operates a gravity-driven regional water system. In addition to the GHG reduction measures that will be implemented as part of all WSIP facility improvement projects,

including the proposed project (see Greenhouse Gas Reduction Actions in Section 3.0, Project Description), the SFPUC is also developing renewable generation and energy-efficiency projects. To date, the SFPUC has constructed several renewable generation projects, and many more are in the planning, design, or construction phases. The SFPUC also manages and implements energy efficiency projects in municipal buildings and facilities, and provides energy efficiency services such as energy audits, design, and construction management. Energy retrofit technologies include installing energy-efficient equipment such as lighting, heating, ventilating, and air conditioning, motors, controls, and energy management systems. The SFPUC is also looking at several sites in the Bay Area for wind power development, and the feasibility of wind power development on CCSF property in the Sierra Nevada foothills is also being considered.

SFPUC GHG Reduction Actions as Part of the Proposed Project. In addition to the actions set forth above, the SFPUC is committed to the following GHG reduction actions as part of the WSIP program.

1. As part of the proposed project, the SFPUC will include the following measures in contractor specifications, which, in addition to having other environmental benefits, would also help reduce GHG emissions.

   A. The SFPUC will require that contractors maintain tire inflation to the manufacturers' inflation specifications.

   B. The SFPUC will implement a construction worker education program.

   C. Contractors who construct new buildings will consult with the SFPUC Power Enterprise's Energy Efficiency Group to incorporate all applicable energy-efficiency measures into the project design. To maximize energy efficiency, the design will attempt to exceed Title 24 minimum requirements by at least 20 percent. Project building components will attempt to meet or exceed Leadership in Energy and Environmental Design Silver certification as required by the CCSF's Green Building Ordinance.

2. This EIR also includes mitigation measures that would be implemented as part of the proposed project, and some of these measures would also help reduce project-related GHG emissions. They include SJVAPCD exhaust control measures (speed limit restrictions, idling restrictions, activity management, and proper equipment maintenance) and incorporation of energy efficiency measures. In addition, CARB regulations (Title 13 of the California Code of Regulations, Sections 2480 and 2485), which limit idling of diesel-fueled commercial motor vehicles, would help to limit GHGs associated with project-related construction vehicles.

4.9.4 Impacts

Significance Criteria

The CCSF has not formally adopted significance thresholds or guidance for making impact determinations related to air quality, but generally considers that implementation of the proposed project would have a significant air quality impact if it were to:

- Conflict with or obstruct implementation of the applicable air quality plan;
- Violate any air quality standard or contribute substantially to an existing or projected air quality violation;
- Conflict with the state goal of reducing GHG emissions in California to 1990 levels by 2020, as set forth by the timetable established in AB 32, California Global Warming Solutions Act of 2006, such that the project's GHG emissions would result in a substantial contribution to global climate change;
- Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is in nonattainment under an applicable federal or state ambient air quality standard (including releasing emissions that exceed quantitative thresholds for O_3 precursors);
- Expose sensitive receptors to substantial pollutant concentrations; or
- Create objectionable odors affecting a substantial number of people.

Areas of No Project Impact

At the Thomas Shaft site, the proposed project would not result in any increase in air emissions over existing conditions during operation. Project operation at the Thomas Shaft site would not require an emergency generator, diesel tanks, nor result in any increase in the number of employees required onsite. Therefore, these operational emissions categories would not apply to the Thomas Shaft site, and at this site, the significance criteria associated with operational emissions would not be applicable. Additionally, the treatment system at the Thomas Shaft site is enclosed, and no new potential odor sources would be generated by the project at this site. Therefore, the significance criterion associated with odors would not be applicable at the Thomas Shaft site and is not discussed further.

Approach to Analysis

The proposed project is located in San Joaquin County, which is under the jurisdiction of the SJVAPCD. CEQA Guidelines allow counties and air districts to develop significance thresholds for both short-term (construction) and long-term (operational) air pollutant emissions. Therefore, significance determinations are based on guidance provided by the SJVAPCD's GAMAQI, CEQA Guidelines, and CARB guidelines.

The proposed project would result in construction emissions, but it is not expected to have any substantive increase in operational (long term, continual) emissions.

As stated in the GAMAQI, "The entire SJVAB is a serious nonattainment area for PM_{10} and any addition to the current PM_{10} problem could be considered significant. However, the SJVAPCD has established regulations governing various activities that contribute to the overall PM_{10} problem. The SJVAPCD has adopted a set of PM_{10} Fugitive Dust Rules collectively called Regulation VIII. Several components of Regulation VIII specifically address fugitive dust generated by construction related activities. Therefore, the SJVAPCD has determined that any determination of significance with respect to construction emissions should be based on a consideration of the control measures to be implemented. From the perspective of the SJVAPCD, compliance with Regulation VIII for all sites and implementation of all other control measures indicated in Tables 6-2 and 6-3 of Regulation VIII (as appropriate, depending on the size and location of the project site) will constitute sufficient mitigation to reduce PM_{10} impacts to a level considered less than-significant" (SJVAPCD, 2002). In accordance with the GAMAQI, this approach is used for the analysis of construction impacts.

The SJVAPCD guidelines provide significance thresholds for criteria pollutant emissions associated with project operations (Table 4.9-4). However, the proposed project would only result in minimal increases in operational emissions over existing conditions resulting from: programmatic testing and emergency operation of emergency generators, minor increases from diesel tank emissions, minor increases in employee and maintenance vehicle emissions, and minor increases in vehicle hauling emissions. Therefore, operational emissions associated with the proposed project are discussed qualitatively.

The presentations of impacts below are shown individually for each project site for ease of presentation. However, it is important to note that the combined effects (the contributions from Thomas Shaft and Tesla Portal together) for each impact were also evaluated. The combined impacts resulting from contributions of the Tesla Portal and Thomas Shaft sites for each impact are the same as the project site specific impact findings.

Construction Impacts

Construction of the proposed project would result in short-term impacts to the existing air quality in the project area. These impacts would include temporary increases of CO, CO_2e, NO_X, PM_{10}, $PM_{2.5}$, SO_X, and ROG emissions at both the Tesla Portal and the Thomas Shaft sites. Emissions resulting from the construction of this project are broadly categorized as follows:

- Equipment exhaust (CO, CO_2e, NO_X, PM_{10}, $PM_{2.5}$, SO_X, and ROG);
- Fugitive dust from earth moving (PM_{10}, $PM_{2.5}$);
- Employee vehicle emissions (CO, CO_2e, NO_X, PM_{10}, $PM_{2.5}$, SO_X, and ROG);
- Construction truck emissions (CO, CO_2e, NO_X, PM_{10}, $PM_{2.5}$, SO_X, and ROG); and

- Paving emissions (ROG).

Equipment exhaust emissions are generated from the combustion of fuels used for the operation of construction equipment. Fugitive dust emissions are generated by the suspension of particulate during earth-moving activities. Employee vehicle emissions and construction truck emissions are generated from the combustion of fuels and from the entrainment of road dust during travel along roadways on site and off site of the construction area. Asphalt paving emissions are generated from the evaporation of regulated volatiles, or diluents, used to liquefy asphalt cement. Reasonable worst-case uncontrolled construction emissions are summarized in Table 4.9-5.

TABLE 4.9-5
REASONABLE WORST-CASE ANNUAL UNCONTROLLED EMISSIONS AT THE TESLA PORTAL SITE DURING CONSTRUCTION (TONS PER YEAR)

Project Component	ROG	NO_x	CO	SO_2	PM_{10} (Dust)	PM_{10} (Exhaust)	PM_{10} Total	$PM_{2.5}$ (Dust)	$PM_{2.5}$ (Exhaust)	$PM_{2.5}$ Total	CO_2

Please refer to Chapter 3, Project Description, for more detailed project information regarding construction schedules, duration, size, etc.

Impact 4.9-1: Construction emissions of criteria pollutants (Tesla Portal: PSM; Thomas Shaft: PSM)

As stated above, the SJVAB is a serious nonattainment area for $PM_{10.}$ Therefore, any addition to the current levels of PM_{10} emissions could be considered potentially significant. The SJVAPCD considers PM_{10} to be the pollutant of greatest concern when evaluating construction emissions. As stated in the GAMAQI, significance of construction emissions should be based on a consideration of the control measures that would be implemented. The SJVAPCD considers implementation of the control measures in Regulation VIII and in Tables 6-2 and 6-3 (when applicable) of the GAMAQI sufficient mitigation to reduce PM_{10} impacts to a level considered less than significant.

The SJVAPCD focuses significance determinations on PM_{10} emissions. However, equipment exhaust emissions are also a concern during construction. The SJVAPCD suggests that CEQA Lead Agencies seeking to reduce emissions from construction equipment exhaust should consider implementing the mitigation measures outlined in Table 6-4 of the GAMAQI. As stated in the

GAMAQI, "The SJVAPCD recognizes that these measures are difficult to implement due to poor availability of alternative fueled equipment and the challenge of monitoring these activities" (SJVAPCD, 2002). Additionally, mitigation required by Regulation IX (Mobile and Indirect Sources, Rule 9510) is applied to the proposed project.

Tesla Portal

Details regarding the size, scope, and length of construction for the Tesla Portal site are outlined in the project description (Chapter 3). Chapter 3 also details expected construction equipment that will be operational throughout build out. In general, construction at this location is anticipated to start in January 2009 and last approximately 24 months.

Construction at the Tesla Portal site would create an increase in short-term emissions of criteria pollutants and precursors, specifically PM_{10}. SJVAB is a nonattainment area for $PM_{10.}$ Therefore, any addition to the current levels of PM_{10} emissions would be considered a potentially significant impact under the guidance of GAMAQI. However, as described above, the SJVAPCD considers

PM_{10} to be the pollutant of concern when evaluating impacts from construction; the SJVAPCD also considers implementation of the control measures in Regulation VIII and in Tables 6-2, 6-3, and 6-4 of the GAMAQI sufficient mitigation to reduce PM_{10} impacts to a level considered less than significant.

In accordance with SFPUC Standard Construction Measure #3, a dust control plan would be prepared and several dust control measures would be implemented.

- In accordance with the guidance outlined in the GAMAQI, the SFPUC would implement Mitigation Measures 4.9-1a and 4.9-1b, which require a host of actions that the SJVAPCD has determined will reduce fugitive dust (PM) emissions and equipment exhaust emissions. These measures include, but are not limited to: stabilization of dust emissions, hauling restrictions, track out restrictions, speed restrictions, idling restrictions, and activity management. See Section 5.2.5 for a specific listing of these actions. Implementation of fugitive dust control measures alone would result in a reduction in PM_{10} dust-related emissions by 40 percent and $PM_{2.5}$ emissions by 38 percent. Total PM_{10} and $PM_{2.5}$ emissions would be reduced (by 7 and 2 percent, respectively) related to construction emissions at the Tesla Portal site (URS, 2008). Implementation of all of the measures included in Mitigation Measures 4.9-1a and 4.9-1b would reduce the potentially significant air quality impact associated with project construction emissions of criteria pollutants at the Tesla Portal site to less than significant.

Thomas Shaft

- Details regarding the size, scope, and length of construction for the Thomas Shaft site are outlined in the project description (Chapter 3). Chapter 3 also details expected construction equipment that will be operational throughout build out. In general, construction at this location is anticipated to start July 2009 and last for approximately 6 months. The development footprint at the Thomas Shaft site is below the SJVAPCD's Rule 9510 threshold triggering the need for quantification and therefore emissions have not been calculated but are discussed qualitatively.

Construction at the Thomas Shaft site would be minimal (trenching for a shallow pipeline, and installation of a prefabricated building and percolation tank) and would create an increase in short-term emissions of criteria pollutants and precursors, specifically PM_{10}. SJVAB is a nonattainment area for $PM_{10.}$ Therefore, any addition to the current levels of PM_{10} emissions could be considered potentially significant under the guidance of GAMAQI. SJVAPCD considers PM_{10} to be the pollutant of concern when evaluating impacts from construction; the SJVAPCD also considers implementation of the control measures in Regulation VIII and in Tables 6-2, 6-3, and 6-4 of the GAMAQI sufficient mitigation to reduce PM_{10} impacts to a level considered less than significant.

In accordance with SFPUC Standard Construction Measure #3, a dust control plan would be prepared and several dust control measures would be implemented.

In accordance with the guidance outlined in the GAMAQI, the SFPUC would implement Mitigation Measures 4.9-1a and 4.9-1b, which require a host of actions that the SJVAPCD has determined will reduce fugitive dust (PM) emissions and equipment exhaust emissions. These measures include, but are not limited to: stabilization of dust emissions, hauling restrictions, track out restrictions, speed restrictions, idling restrictions, and activity management. See Section 5.2.5 for a specific listing of these actions. Implementation of these mitigation measures would reduce

the potentially significant air quality impacts of construction at the Thomas Shaft site to less than significant.

Impact 4.9-2: Exposure to DPM during construction (Tesla Portal: LS; Thomas Shaft: LS)

Diesel exhaust is generated from the operation of diesel-fueled construction equipment and vehicles (i.e., diesel construction equipment, delivery/haul trucks, and worker commute vehicles). Of the TACs found in diesel exhaust, the primary TAC of concern is DPM. The SJVAPCD provides the following two thresholds for evaluating significance for TACs in the GAMAQI. It should be noted that these are generally only applied towards a project's operational emissions, as the risks associated with TACs are evaluated for a project's long- term operational emissions; because "for cancer health effects, risk is expressed as an estimate of the increased chances of getting cancer due to facility emissions over a 70-year lifetime. This increase in risk is expressed as chances in a million (e.g., 10 chances in a million)" (CARB, 2005). The effects of TACs would be significant if:

- The probability of contracting cancer for the Maximally Exposed Individual (MEI) exceeds 10 in one million.
- The ground-level concentrations of non-carcinogenic TACs would result in a Hazard Index greater than 1 for the MEI.

Tesla Portal Site

The only DPM emitting construction activities at the Tesla Portal site would be the use of diesel-fueled construction equipment, hauling vehicles, and diesel-fueled employee (construction) vehicles. There is an on-site caretaker residence (see Figure 3-1 in Section 3.0) within the project boundary. The closest off-site residential structure to the Tesla Portal site is located approximately 2,500 feet to the southeast of the project area, off West Vernalis Road. Additionally, the community of Chrisman is approximately 0.75 miles east of the Tesla Portal site (off-site) and is adjacent to the project hauling route.

Based on minimum separation distances recommended by CARB for other DPM emitting sources and sensitive land uses (*Air Quality and Land Use Handbook: A Community Health Perspective* [CARB, 2005]), the location of the off-site receptors would not be considered at risk for chronic exposure to the Tesla Portal on-site construction-related DPM emissions.

Construction at the Tesla Portal site would take approximately 24 months. Throughout this time, diesel particulate emissions would be generated from hauling along specified routes (see Section 4.8 Traffic, Transportation, and Circulation) and from diesel fueled construction equipment. Construction employee vehicle emissions would be minor. Diesel emissions would be inconsistent and would vary depending on the nature of the day's particular activities. Over the 24 month construction period, construction activities would increase DPM emissions temporarily over existing conditions. However, the time frame and frequency of exposure to DPM emissions is short in duration when the temporary and incremental increases are averaged over the 70 years over which cancer risk is evaluated. As such, the off-site and on-site receptors would not be considered at risk for chronic exposure to the Tesla Portal construction-related DPM emissions (including those located along haul routes).

Due to the short-term and variable nature of the construction DPM-emitting activities (compared to a 70-year exposure scenario) and the proximity of sensitive receptors to the Tesla Portal site, it is not expected that any sensitive receptors would be exposed to significant annual (chronic long-term) concentrations of DPM. The cancer risk associated with DPM would be below the threshold listed above. Therefore, the impact of DPM from construction at the Tesla Portal site is considered to be less than significant.

Furthermore, in accordance with Mitigation Measure 4.9-1b (exhaust control measures) required to mitigate Impact 4.9-1, all construction equipment with engines equal to or greater than 50 horsepower would:

- Be equipped with verified Level 3 (at least 85 percent reduction of PM from the baseline emission level) Diesel Emission Control Strategies as defined in Title 13, CCR, §2700 through 2710;

- Be equipped with Tier 2 diesel engines as defined in Title 13, CCR, §2423; and

- Minimize idling (vehicles) to 5 minutes, in accordance with Title 13, CCR, §2485.

Thomas Shaft

The only DPM emitting construction activities at the Thomas Shaft site would be the use of diesel-fueled construction equipment, hauling vehicles, and diesel-fueled employee (construction) vehicles. There are no sensitive receptors in the immediate vicinity of the Thomas Shaft site. The closest residential structure to the Thomas Shaft site (according to aerial photographs), is a rural residence about 1.25 mile to the northeast of the site. The location of this receptor would not be considered at risk for chronic exposure to the Thomas Shaft on-site construction-related DPM emissions (CARB, 2005).

It is likely that receptors would be located adjacent to haul roads at some point along the specified routes (see Section 4.8 Traffic, Transportation, and Circulation). As detailed above, the time frame and frequency of exposure to hauling emissions would be short in duration when the temporary and incremental increases are averaged over the 70 years over which cancer risk is evaluated. As such, any receptors adjacent to haul routes would not be considered at risk for chronic exposure to the Thomas Shaft construction-related DPM emissions from hauling.

Construction at the Thomas Shaft site would take approximately 6 months. Due to the short-term nature of the construction DPM-emitting activities (compared to a 70-year exposure scenario) and the proximity of the closest sensitive receptor to the Thomas Shaft site, it is not expected that any sensitive receptors would be exposed to significant annual (chronic long-term) concentrations of DPM. The cancer risk associated with DPM would be below the threshold listed above. Therefore, the impact of DPM from construction at the Thomas Shaft site is considered to be less than significant. Mitigation Measure 4.9-1b, required to mitigate Impact 4.9-1, would also be implemented at this site.

Operational Impacts

Operation of the proposed project would result in long-term impacts to the existing air quality in the project area. These impacts would include minor increases of CO, CO_2e, NO_X, PM_{10}, $PM_{2.5}$, SO_X, and ROG emissions. Emissions resulting from the operation of this project are broadly categorized as follows:

- Emergency generator exhaust (CO, CO_2e, NO_X, PM_{10}, $PM_{2.5}$, SO_X, and ROG);
- Diesel tank emissions (ROG); and
- Vehicle emissions (CO, CO_2e, NO_X, PM_{10}, $PM_{2.5}$, SO_X, and ROG).

- All operational exhaust emissions are generated from the combustion of fuels. Diesel tank emissions are generated from the displacement of volatile vapors during refilling and the evaporation of volatiles. Reasonable worst-case uncontrolled operations emissions are summarized in Table 4.9-6.

TABLE 4.9-6
REASONABLE WORST-CASE ANNUAL UNCONTROLLED EMISSIONS ESTIMATES AT THE TESLA PORTAL SITE DURING OPERATIONS (TONS PER YEAR)

Source	ROG	NO_X	CO	SO_2	PM_{10}	CO_2
Emergency Generator	0.0553	1.0515	0.5996	0.0009	0.0346	82.5757
Transportation	0.0014	0.0274	0.0210	0.0001	0.00069	9.6761
Diesel Tanks	0.0343	--	--	--	--	--
Total	**0.0911**	**1.0789**	**0.6206**	**0.0009**	**0.0353**	**92.2518**

Source: URS, 2008

Impact 4.9-3: Air pollutant emissions during project operation (Tesla Portal: LS, Thomas Shaft: N/A)

Operational emissions from the proposed project are considered to be minor. They are broadly grouped into the following 5 categories: emissions from new emergency generators, emissions from diesel tanks, employee vehicles, maintenance vehicle trips, and chemical delivery vehicles. Each category, as it applies to each site, is discussed below. Indirect emissions resulting from the proposed project's increased power demands are discussed separately in Impact 4.9-6.

Tesla Portal

Operation of the Tesla Treatment Facility would include the use of two new 1,500 kW emergency generators. Typically, emergency generators comprise a fuel storage tank and an internal combustion engine. Emergency generators are stationary sources and are only operated for programmatic testing and in emergency situations—specifically, power outages. Operation of the Tesla Treatment Facility would result in a minor increase in criteria pollutant and precursor emissions associated with the programmatic testing and emergency operation of the generators. Stationary source generator emissions would be infrequent, short-term events. As such, emissions from the emergency generators would be minor in any given year of operation.

Two 15,000-gallon diesel fuel tanks would be installed at the Tesla Portal site to support the emergency generators. Minor ROG emissions would result from the refilling of the diesel tanks at the Tesla Portal site, as vapors inside the tank are displaced to the atmosphere by liquid. Additionally, evaporative emissions (losses) would occur as the tanks vent throughout the year in response to heating and cooling temperatures. Evaporative emissions from diesel fuels are generally minor due to the fuel's low volatility. Furthermore, the tanks would only need to be

refilled periodically following emergency operation, programmatic testing, or top off. As such, the increase in emissions associated with the diesel tanks would be minor.

A minor increase in mobile source emissions would result from the addition of two new full-time employees at the Tesla Portal site. Employees at the Tesla Portal site would only be onsite intermittently, as needed. As such, additional emissions would result from two intermittently used employee vehicles. The criteria pollutant and precursor emissions from these vehicles would be minor. The increase in employee vehicle trips is estimated at 2 vehicle round trips per day, as shown in Section 4.8, Traffic, Transportation, and Circulation.

The Tesla Treatment Facility would also require additional diesel vehicle trips for maintenance and delivery activities. These vehicle trips would be required for routine maintenance and to deliver virgin chemicals and fuel to the site. The increase in maintenance and delivery vehicle trips is summarized in Section 4.8, Traffic, Transportation, and Circulation and is estimated at 5

vehicle round trips per day. These increased vehicle trips do not represent a significant increase in criteria pollutant and precursor emissions over existing conditions.

The emissions resulting from the operation of the proposed facilities at the Tesla Portal site would be below SJVAPCD thresholds (10 tons/year NO_X and ROG) and the impact is considered less than significant.

Impact 4.9-4: Exposure to diesel particulate matter during operation (Tesla Portal: LS; Thomas Shaft: N/A)

Tesla Portal Site

The only operational DPM emitting activities at the Tesla Portal site would be the use of diesel-fueled chemical delivery trucks and the sporadic operation of the emergency diesel generators.

Diesel delivery trucks are estimated to make 5 vehicle round trips per day. This represents a minor increase in DPM emissions over existing conditions. The use of emergency diesel generators would also be very limited; emissions in any given year are expected to be insignificant. Due to the minor increase in operational DPM-emitting activities and the proximity of the off-site receptors to the Tesla Portal site, it is not expected that any receptors (including the care takers residence and those adjacent to haul routes) would be exposed to significant annual (chronic long-term) concentrations of DPM from this activity. The cancer risk associated with DPM would be below the threshold listed for impact 4.9-2. Therefore, the impact of operational DPM is considered less than significant.

Impact 4.9-5: Odors generated during project operation (Tesla Portal: LS; Thomas Shaft: N/A)

Tesla Portal Site

The proposed treatment system at the Tesla Portal site would be enclosed, with the exception of the 90,000-gallon containment basin. Potential odor sources at the Tesla Portal site are as follows: three 16,000-gallon sodium hypochlorite tanks, two 15,000-gallon diesel fuel tanks, and a septic tank and leach field system.

Sodium hypochlorite has a characteristic odor, similar to bleach or chlorine. The largest release of sodium hypochlorite vapors would occur during the routine filling of the tanks, as vapors are displaced by liquid. However, this release would be minor as filling of the tanks would be infrequent, occurring on the magnitude of 0 to 4 times per month. Sodium hypochlorite would be used in the treatment system at the Tesla Portal site. Under normal operation, there would not be any odors associated with the addition of sodium hypochlorite to the water supply, as it is an

enclosed system. As such, the storage and use of sodium hypochlorite would not be a significant source of odors.

Diesel fuel has a characteristic petroleum distillate odor. The largest release of diesel vapors/odors would result from the refilling of the diesel tanks at the Tesla Portal site, as vapors inside the tank are displaced to the atmosphere by liquid. Additionally, the tanks would vent vapors/odors throughout the year as volatiles evaporate in response to heating and cooling temperatures. Evaporative losses from diesel fuel are generally minor due to the fuel's low volatility. Furthermore, the tanks would only need to be refilled periodically following emergency operation, programmatic testing, or top off. As such, the storage and use of diesel fuel would not be a significant source of odors.

Septic tanks generally vent hydrogen sulfide and other unpleasant odorous compounds that are generated from the anaerobic decomposition of waste in the tank. These odors are emitted through an elevated vent that aids in the rapid dispersion of the odors so that they are not detected on the ground by humans. When odors are detected from a septic tank and leach field system, it is generally a clear indication that the system is operating improperly. The septic tank at the Tesla Portal site would be installed and maintained properly and would not be a significant source of odors.

The above odor sources would all be installed, vented, and maintained in accordance with applicable regulations and therefore would not be significant sources of odors. Therefore, odors wouldn't affect the nearest sensitive receptors and the impact of odors from the Tesla Portal site is considered less than significant.

Impact 4.9-6: Indirect emissions at power plants from project operation (Tesla Portal: LS; Thomas Shaft: LS)

Tesla Portal Site

The Tesla Portal site would have an increased power demand over that of existing operational demands. This increased power demand would be a direct result of new electrical equipment that would be installed at the Tesla Portal site. A description of this new electrical equipment is detailed in Chapter 3.0 (Project Description).

The capacity to provide power to the Tesla Portal site would be present in the existing electrical grid feeding the Tesla Portal site. That existing electrical grid power is primarily provided by SFPUC Power Enterprise, but is distributed to the site by PG&E. SFPUC Power Enterprise primarily generates their power from hydroelectric sources, although they also purchase power that is derived from a variety of sources, including hydroelectric, alternative energy, and fossil fuels. All of these existing local power-generating facilities have been licensed to operate

depending on the varying supply and demand in the regional electrical grid at any one point in time.

As such, the increased power demand from the Tesla Portal site would not exceed allowable emission rates of local power generating facilities. The local power generating facilities serving the existing grid at the Tesla Portal site have previously gone through California's stringent regulatory processes to ensure minimum environmental impacts, specifically including air quality.

Additionally, as stated in Section 4.14, Energy Resources, the SFPUC has consulted with the Power Enterprise Energy Efficiency Group and would incorporate their "Recommended Energy Use Guidelines" into the design of the Tesla Portal site. The SFPUC may also consider the use of solar power at the Tesla Portal site in the future; however, solar panels are not currently proposed as part of the project and if solar panels were installed at Tesla Portal, they would be added after completion of all construction activities at the site.

The Tesla Portal site would operate within the existing electrical grids confines. Therefore, the incremental increase in power demand during operation of the Tesla Portal site would result in an indirect air quality impact that is less than significant on criteria air pollutant levels.

Thomas Shaft Site

The Thomas Shaft site would have an increased power demand over that of existing operational demands. This increased power demand would be a direct result of new electrical equipment that would be installed at the Thomas Shaft site. The capacity to provide power to the Thomas Shaft site would be present in the existing electrical grid feeding the Thomas Shaft site. Therefore, the incremental increase in power demand during operation of the proposed project at the Thomas Shaft site would result in an indirect air quality impact that is less than significant on criteria air pollutant levels.

Impact 4.9-7: Conflict with implementation of applicable regional air quality plans addressing criteria air pollutants and state goals for reducing GHG emissions (Tesla Portal: LS; Thomas Shaft: LS)

Regional Plans

This impact relates to the regional effect of the project. Therefore, the contributions of each site (Tesla Portal and Thomas Shaft) are not discussed separately. Instead, the regional impact of the project as a whole is assessed qualitatively.

Plans adopted by the SJVAPCD anticipate that new stationary sources would locate within the SJVAPCD in future years (and that existing sources would expand operations) and seek authority to emit air pollutants under the SJVAPCD Rule 2201 (New and Modified Stationary Source

Review Rule). To allow for such future economic growth, the plans anticipate that stationary sources would seek approvals from the SJVAPCD and would be required to provide emission reduction credits to offset (or mitigate) emission increases. The result of the offset program is that the net increase of emissions within the SJVAPCD from stationary sources would be zero.

If applicable, SFPUC would be required to seek approval for its proposed project under SJVAPCD Rule 2201 and provide emission reduction credits for the stationary emergency generators if required to do so by the rule. Stationary source emissions would therefore be consistent with the SJVAPCD adopted air quality plans and impacts to regional air quality are considered less than significant.

State GHG Goals

This impact relates to the state-wide effect of GHGs from the proposed project. Therefore, the contributions of each site (Tesla Portal and Thomas Shaft) are not discussed separately. Instead, the state-wide impact (as it relates to GHG emissions) of the project as a whole is assessed.

The California Air Pollution Control Officers Association (CAPCOA) recently released a resource guide addressing GHG emissions from projects subject to CEQA. However, the "paper is intended as a resource, not a guidance document. It is not intended, and should not be interpreted, to dictate the manner in which an air district or lead agency chooses to address greenhouse gas emissions in the context of its review of projects under CEQA." (CAPCOA, 2008)

The resource guide specifies that there are "basic options air districts and lead agencies can pursue when contemplating the issues of CEQA thresholds for greenhouse gas emissions" (CAPCOA, 2008). The resources guide "explores each path and discusses the benefits and disbenefits of each." The three basic paths suggested in this resource guide are:

- No significance threshold for GHG emissions;
- GHG emissions threshold set at zero; or
- GHG emissions threshold set at a non-zero level.

Although progress is being made and several approaches for evaluating GHG impacts are being discussed, no clear methodology has been established (CAPCOA, 2008). The decision of which approach to take must be scientifically based; and a clear scientific threshold (zero or non-zero) or basis for a threshold has yet to be determined. As such, no air district or lead agency in California, including the SJVAPCD, has identified a significance threshold for GHG emissions or a methodology for analyzing air quality impacts related to GHG emissions. However, this does not relieve any lead agency from the responsibility of addressing and assessing GHG impacts from proposed projects.

The Governor's Office of Planning and Research (OPR) is responsible for adopting regulations implementing CEQA; that agency has not yet promulgated any regulations directly concerning

analysis of global climate change, but has published a technical advisory document that provides guidance specific to addressing GHG emission in CEQA documents. This document does not establish thresholds, but provides guidance on what factors to consider when analyzing the impacts of a proposed project on global climate change (OPR 2008). CARB is the state-wide agency responsible for administering air quality programs within the state, and has been tasked with developing many of the regulatory programs required by AB 32, but CARB likewise has not developed any regulations regarding evaluation of global climate change within CEQA documents. The SJVAPCD is the regional agency responsible for regulating air emissions within the project area, but has yet to develop guidance regarding evaluation of global climate change within CEQA documents.

In the absence of adopted regulations and thresholds, this report patterns its global climate change analysis on available guidance and a qualitative analysis demonstrating that the projects impacts would not conflict with the state goal of reducing GHG emissions in California to 1990 levels by 2020, as set forth by the timetable established in AB 32 (California Global Warming Solutions Act of 2006).

With this approach, it is possible to conclude that if all feasible and applicable emissions reduction strategies are implemented, the GHG impact of the proposed project is considered less than significant.

Construction

The current statewide annual net GHG inventory is estimated at 479.74 million metric tons of CO_2e (CARB, 2007b). CARB staff resolved an amount of 427 million metric tons of CO_2e as the total statewide greenhouse gas 1990 emissions level and 2020 emissions limit. The limit is a cumulative statewide limit, not a sector or facility specific limit (CARB, 2007a). Therefore, the state's goals are to reduce GHG emissions by 52.74 million metric tons of CO_2e by the year 2020.

The proposed project's reasonable worst-case annual construction emissions of GHG are estimated at 5,289 metric tons of CO_2e per year. This number includes emissions from construction equipment, material hauling vehicles, and construction employee vehicles. The current statewide annual net GHG inventory is estimated at 479.74 million metric tons of CO_2e per year (CARB, 2007b). Therefore, the reasonable worst-case annual uncontrolled emission of GHG from construction activities would represent only 0.0011 percent of the statewide total. Based on this result, it is evident that GHG emissions from construction of the proposed project would be minor in comparison to the state total.

Additionally, construction emissions are transient and temporary. Therefore, once construction of the proposed project is over, GHG emissions generated by the project's construction activities would cease. Mitigation Measure 4.9-1b, required to mitigate Impact 4.9-1, would reduce the emissions generated from all construction equipment exhaust and is consistent with federal and

state emission reduction strategies. Furthermore, existing CARB regulations (Title 13 of the California Code of Regulations, Sections 2480 and 2485) and Early Action Measures (pursuant to the California Global Warming Solutions Act of 2006) would require emission reduction measures for diesel trucks and diesel off-road equipment. CARB would review and adopt Early Action Measures by January 1, 2010, and equipment used for the construction of the proposed project could be subject to these requirements. SFPUC would implement these measures as required.

Given the minor amount (comparatively) of GHG that would be emitted during construction of the proposed project, implementation of Mitigation Measure 4.9-1b (which outlines measures for exhaust control), continuing compliance with federal and state GHG regulations, and continuing implementation of GHG reduction actions by the CCSF and SFPUC and additional GHG reductions actions that SFPUC would implement as part of the proposed project (described under the Setting), construction of the proposed project would not conflict with the state goal of reducing GHG emissions in California to 1990 levels by 2020, as set forth by the timetable established in AB 32 (California Global Warming Solutions Act of 2006). Therefore, the impact during project construction is considered less than significant.

Operations

Operational GHG emissions from the proposed project would be minor. GHG emissions would be generated from three sources: (1) programmatic testing and operation of emergency generators; (2) operation of vehicles that would be used for employees, deliveries, and to carry out routine maintenance activities; and (3) indirect emissions from power plants due to increased power demand from project operation. The Tesla Portal site would have two CO_2 tanks on site that would be used to lower pH. The CO_2 would be injected into the water and would be consumed by the water. Therefore, there are no CO_2 emissions generated by this process.

Though not quantified, emissions from the infrequent use of the emergency generators and emissions from operational vehicles would be minor. Future compliance with federal and state regulations regarding stationary and mobile sources would help to ensure that these sources are in compliance and do not conflict with the state's goals of reducing GHG emissions to 1990 levels by 2020.

Similarly, for the reasons described above in Impact 4.9-6, the GHGs that would be indirectly emitted from power generating facilities supporting the proposed project is also considered to be less than significant.

Given the very minor amount of GHG that would be emitted during operation of the proposed project, compliance with federal and state stationary source regulations (if applicable), continuing compliance with federal and state GHG regulations, and continuing implementation of GHG reduction actions by the CCSF, operation of the proposed project would not conflict with the state goal of reducing GHG emissions in California to 1990 levels by 2020, as set forth by the timetable established in AB 32 (California Global Warming Solutions Act of 2006). Therefore, the impact during project operation is considered less than significant.

4.10 Noise and Vibration

4.10.1 Setting

Noise and Vibration Terminology

Noise is commonly defined as unwanted sound that annoys or disturbs people and potentially causes an adverse psychological or physiological effect on human health. Because noise is an environmental pollutant that can interfere with human activities, evaluation of noise is necessary when considering the environmental impacts of a proposed project.

The effects of noise on people can be grouped into three categories: (1) subjective effects of annoyance, nuisance and dissatisfaction; (2) interference with such activities as speech and sleeping; and (3) physiological effect, such as hearing loss.

Sound is measured in decibels (dB). Although decibels describe the purely physical amplitude of sound, they cannot accurately describe sound as perceived by the human ear, because the human ear is only capable of hearing sound within certain frequency ranges. The frequency of sound must be taken into account when evaluating the potential human responses. For this reason, a frequency-dependent weighting system is used and the results reported in A-weighted decibels (dBA). Decibels and other technical terms are defined in Table 4.10-1. Typical A-weighted noise levels are shown for different noise sources in Table 4.10-2.

An important method for determining a person's subjective reaction to a new noise is by comparing it to ambient (existing) conditions. The following describes the general effects of noise on people (Harris, 1998):

- A change of 1 dBA cannot typically be perceived, except in carefully controlled laboratory experiments
- A 3-dBA change is generally considered a just-perceivable difference
- A minimum of 5-dBA change is required before any noticeable change in community response is expected
- A 10-dBA change is subjectively perceived as approximately a doubling or halving in loudness

In unconfined space, such as outdoors, noise attenuates with distance according to the inverse square law. Noise levels at a known distance from point sources are reduced by 6 dBA for every doubling of that distance for hard surfaces, such as cement or asphalt surfaces, and 7.5 dBA for every doubling of distance for soft surfaces, such as undeveloped or vegetative surfaces (Caltrans, 1998). Noise levels at a known distance from line sources, such as roadways, theoretically decrease at a rate of 3 dBA for every doubling of the distance for hard surfaces and 4.5 dBA for every doubling of distance for soft surfaces (Caltrans, 1998). A greater decrease in noise levels can result from the presence of intervening structures or buffers.

TABLE 4.10-1
DEFINITIONS OF ACOUSTICAL TERMS

Term	Definition
Decibel (dB)	A unit describing the amplitude of sound, equal to 20 times the logarithim to the base 10 of the ratio of the pressure of the sound measured to the reference pressure, which is 20 micropascals (20 micronewtons per square meter). Sound described in decibels is usually referred to as Sound and Noise "Level".
Frequency: Hertz (Hz)	The number of complete pressure fluctuations per second above and below atmospheric pressure.
A-Weighted Sound Level (dBA)	The sound pressure level in decibels as measured on a sound level meter using an A-weighted filter network. The A-weighting filter de-emphasizes the very low and very high frequency components of the sound in a manner similar to the frequency response of the human ear and correlates well with subjective reactions to noise.
L01, L10, L50, L90	The average A-weighted noise levels that are exceeded 1, 10, 50 and 90 percent of the time during the measurement period.
Equivalent Noise Level (L_{eq})	The energy average A-weighted noise level during the measurement period.
Community Noise Equivalent Level (CNEL)	The energy average A-weighted noise level during a 24-hour day, obtained after addition of 5 dB in the evening (7:00 to 10:00 p.m.) and after addition of 10 dB to sound levels during the night (10:00 p.m. to 7:00 a.m.).
Day/Night Noise Level (L_{dn})	The energy average A-weighted noise level during a 24-hour day, obtained after addition of 10 dB to levels measured in the night (10:00 p.m. and 7:00 a.m.).
L_{max}, L_{min}	The maximum and minimum A-weighted noise level during the measured period.
Ambient Noise Level	The composite of noise from all sources near and far. The normal or existing level of environmental noise at a given location.
Intrusive	Noise that intrudes over and above the existing ambient noise at a given location. The relative intrusiveness of a sound depends on its amplitude, duration, frequency, and time of occurrence and tonal or informational content as well as the prevailing ambient noise level.
Pure Tone	A pure tone is a single frequency tone with no harmonic content.

TABLE 4.10-2
TYPICAL SOUND LEVELS MEASURED IN THE ENVIRONMENT

Examples of Common, Easily Recognized Sounds	Decibels (dBA)	Subjective Evaluations
Near Jet Engine	140	Deafening
Threshold of Pain	130	
Threshold of Feeling – Hard Rock Band	120	
Accelerating Motor Cycle (at a few feet away)	110	Very Loud
Loud Horn (at 10 feet away)	100	
Noisy Urban Street	90	
Noisy Factory	85[a]	
School Cafeteria with Untreated Surfaces	80	Loud
Stenographic Room	70[b]	
Near Freeway Auto Traffic	60[b]	Moderate
Average Office	50[b]	
Soft Radio in Apartment	40	Faint
Average Residence Without Stereo Playing	30	
Average Whisper	20	Very Faint
Rustle of Leaves in Wind	10	
Human Breathing	5	
Threshold of Audibility	0	

[a] Continuous exposure above 85 dBA is likely to degrade the hearing of most people.
[b] Range of speech is 50 to 70 dBA

Source: U.S. Department of Housing and Urban Development, Office of Community Planning and Development, 1985.

Since decibels are logarithmic units, sound pressure levels cannot be added or subtracted by ordinary arithmetic means. For example, if one automobile produces a noise level of 70 dBA when it passes an observer, two cars passing simultaneously would not produce 140 dB. In fact, they would combine to produce 73 dBA (Caltrans, 1998). When combining sound levels, Table 4.10-3 may be used to approximate the combined result.

TABLE 4.10-3
DECIBEL ADDITION

When The Decibel Values Differ By:	Add This Amount to the Higher Value
0 or 1 dB	3 dB
2 or 3 dB	2 dB
4 to 9 dB	1 dB
10 dB or more	0 dB

Vibration

Vibrations caused by construction activities can be interpreted as energy transmitted in waves through the soil mass. These energy waves generally dissipate with distance from the vibration source. Since vibration energy, like sound energy, is reduced by geometric spreading as it propagates away from its source, vibration that is distant from a source is usually less perceptible than vibration closer to the source. However, actual human and structure response to different vibration levels is influenced by a combination of factors, including soil type, distance between source and receptor, duration, and the number of perceived events.

Perceptible ground-borne vibration is generally limited to areas within a few hundred feet of construction activities. The construction activities that typically generate the most severe vibrations are blasting and impact pile-driving, neither of which is proposed by the project. If great enough, the energy transmitted through the ground as vibration can result in structural damage. To assess the potential for structural damage associated with vibration, the vibratory ground motion in the vicinity of the affected structure is measured in terms of peak particle velocity (PPV) in the vertical and horizontal directions (vector sum), typically in units of inches per second (in/sec). A freight train passing at 100 feet can cause vibrations of 0.1 in/sec PPV, while a strong earthquake can produce vibrations in the range of 10 in/sec PPV. In general, cosmetic or threshold damage to residential buildings can occur at over 0.5 in/sec PPV. The term "threshold damage vibration" is defined as the highest vibration amplitude at which no cosmetic, minor, or major damage occurs, which includes "threshold cracks" or "hairsized" cracks in room walls that occur at the lowest vibration amplitudes.

Agencies such as the Federal Transit Administration (FTA) and the National Park Service (NPS) use PPV as a descriptor because it is related to the stresses experienced by buildings. Although PPV is appropriate for evaluating the potential of building damage, it is not suitable for evaluating human response. Because it takes some time for the human body to respond to vibration signals, a 1-second average velocity is typically used to assess vibration impacts on humans. This average is expressed using decibels, or VdB. The background vibration velocity level in residential areas is usually 50 VdB or lower, well below the threshold of perception for humans, which is approximately 65 VdB. Human response to vibration is usually not significant until it exceeds 70 VdB.

Vibration thresholds vary depending on the nature of the vibration and frequency range. Controlled detonations do not generate structural damage if they produce vibrations of less than 0.5 in/sec PPV (measured at the residential building setback line at the ground surface). This level is consistent with the U.S. Bureau of Mines' threshold cracking criteria of 0.5 in/sec PPV for low frequencies and 2.0 in/sec PPV for high frequencies. Continuous vibration caused by vibratory pile drivers, impact pile drivers, and large vibratory rollers/compactors can cause annoyance but do not cause structural damage if the continuous vibration is less than 0.2 in/sec PPV. This criterion is less than the controlled detonation vibration limit, reflecting the longer exposure time and the potential effect of structural resonances. Vibratory mechanical equipment may be operated over many minutes several times per day, and the associated response of structures can

build up over several seconds due to resonance of the structure, especially during startup and shutdown of vibratory compactors. Impact pile driving, which is not proposed as part of project construction, involves repeated impacts of several hundred per day, much more than occurs for controlled detonations. Thus, the vibration limit for impact pile driving is the same as the threshold for continuous vibration (0.2 in/sec PPV) (Wilson Ihrig & Associates, 2005). Lastly, the FTA's recommended vibration threshold criterion for fragile buildings is 0.2 in/sec PPV (U.S. Department of Transportation, Federal Transit Administration, 1995).

Existing Noise Environment and Sensitive Receptors Locations

Neither site is located within two miles of a public airport or public use airport or is in an area covered by an airport land use plan, and neither site is in the vicinity of a private airstrip.

Sensitive Receptors

Sensitive receptors are identified on land uses where noise-sensitive receptors may be present or where noise-sensitive activities may occur. These areas may require special consideration to achieve protection from excessive noise. Noise-sensitive land uses include residences, schools, hospitals, and retirement homes. Noise-sensitive activities occur in locations such as churches, libraries and recreational areas. No hospitals, medical centers, daycare facilities, colleges, or schools are located near the project sites.

Tesla Portal Site

The noise-sensitive receptors in the vicinity of the Tesla Portal site consist of the residential community of Chrisman approximately 0.75 miles to the east, a residence approximately 2,500 feet to the southeast, and the onsite caretaker's residence.

Thomas Shaft Site

The only noise-sensitive receptor in the vicinity of the Thomas Shaft site consists of a residence approximately 1.25 miles to the northeast. The Lawrence Livermore National Laboratory (LLNL) Site 300, at the intersection of Thomas Shaft Road and Corral Hollow Road, is about 1.5 miles to the north. LLNL Site 300 contains a variety of office buildings and other structures; however, this is not considered a noise-sensitive receptor.

Ambient Noise Levels

An ambient noise survey was not conducted at either the Tesla Portal or Thomas Shaft sites or at any noise-sensitive receptors. However, expected noise levels at those locations can be estimated based on the types of noise sources and distances to those sources using the FTA Transit Noise and Vibration Impact Assessment Manual (U.S. Department of Transportation, Federal Transit Administration 2006). Existing noise levels are estimated by first examining the site's proximity to major roads and railroad lines. If these noise sources are far enough away that ambient noise is dominated by local streets and community activities, the estimate is made based on population density. The decision of which to use is made by comparing the noise levels from each of the three categories, roadways, railroads and population density, and selecting the highest level. The table used to estimate existing noise levels from the FTA Manual is provided below (Table 4.10-4).

Table 4-10.4
Estimate of Typical Roadway Noise Levels

Distance from Major Noise Source[1] (ft)		Population Density (people per sq mile)	Noise Exposure Estimates			
Interstate Highways[2]	Other Roadways[3]		L_{eq} Day	L_{eq} Evening	L_{eq} Night	L_{dn}
10-50			75	70	65	75
50-100			70	65	60	70
100-200			65	60	55	65
200-400			60	55	50	60
400-800			55	50	45	55
800 and up			50	45	40	50
	10-50		70	65	60	70
	50-100		65	60	55	65
	100-200		60	55	50	60

			--	--	--	45
		1-100	35	30	25	35
		100-300	40	35	30	40
		300-1,000	45	40	35	45
		1,000-3,000	50	45	40	50
		3,000-10,000	55	50	45	55
		10,000-30,000	60	55	50	60
		30,000 and up	65	60	55	65

[1] Distances to not include shielding from intervening rows of buildings. General rule for estimating shielding attenuation in populated areas: Assume 1 row of buildings every 100 ft; -4.5 dB for first row, -1.5 dB for every subsequent row up to a maximum of -10 dB attenuation.
[2] Roadways with 4 or more lanes that permit trucks, with traffic at 60 mph.
[3] Parkways with traffic at 55 mph, but without trucks, and city streets with the equivalent of 75 or more heavy trucks per hour and 300 or more medium trucks per hour at 30 mph.
Source: U.S. Department of Transportation, Federal Transit Administration, 2006

Tesla Portal Site

At the Tesla Portal site, existing noise sources consist of the existing water system facilities, including two diesel standby generators and an engine pump; vehicle noise from truck deliveries and workers' vehicles; ranching or farming-related equipment; and vehicle traffic along roadways such as Interstate 580 (I-580), which is approximately 2,600 feet from the property's northern property boundary. Based on the distance from the major highway (I-580), existing noise levels for the Tesla Portal site and all noise-sensitive receptors except for Chrisman were determined assuming a population density of 300 to 1,000 people per square mile. Using this population density, existing noise levels are expected to be approximately 45 dBA L_{dn} (45 dBA L_{eq} daytime, 40 dBA L_{eq} evening, and 35 dBA L_{eq} night) (See Table 4.10-1 for definition of terms). Existing noise levels in the community of Chrisman are expected to be slightly higher because they are located closer to I-580: 50 dBA L_{dn} (50 dBA L_{eq} daytime, 45 dBA L_{eq} evening, and 40 dBA L_{eq} night.

Thomas Shaft Site

At the Thomas Shaft site, existing noise sources consist of the existing water system facilities, including an intermittently operating generator; some vehicle noise from truck deliveries and workers' vehicles; and ranching or farming-related equipment. Because the site is situated in an even more remote rural area than the Tesla Portal site, expected noise levels were estimated using a population density of 100 to 300 people per square mile. Existing noise levels are expected to be 40 dBA L_{dn} (40 dBA L_{eq} daytime, 35 dBA L_{eq} evening, and 30 dBA L_{eq} night).

4.10.2 Regulatory Framework

Noise

Noise standards typically are promulgated at the local level. However, federal and state agencies provide standards and guidelines to local jurisdictions. Local noise issues are addressed through implementation of general plan policies, including noise and land use compatibility guidelines, and through enforcement of noise ordinance standards. General plan policies provide guidelines for determining whether a noise environment is appropriate for a proposed or planned land use. Noise ordinances regulate noise sources, such as mechanical equipment and amplified sounds, as well as prescribe hours of heavy equipment operation. In most cases, noise ordinances are part of local building and zoning ordinances of other jurisdictions; these building and zoning ordinances do not apply to SFPUC projects outside of City and County of San Francisco (CCSF) boundaries (refer to Section 4.2, Plans and Policies). However, time and noise limits prescribed in local noise ordinances are used in this EIR as criteria to determine the significance of project impacts under CEQA.

San Joaquin County Noise Limits

The project sites are located in unincorporated San Joaquin County. The San Joaquin County Development Title implements the land use policies of the San Joaquin County General Plan and functions as the County's zoning ordinance, containing regulations governing the use of land and improvement of real property within zoning districts. The County Development Title limits construction activities to specific hours of the day, and specifies noise limits for the operation of stationary equipment.

Construction Noise

The County Development Title does not specify noise exposure limits for construction activities, but construction activities are limited to between 6:00 a.m. and 9:00 p.m., on both weekdays and weekends (San Joaquin Development Title, Section 9-1025.9(c)(3)).

No sound level limits for construction noise are set in the San Joaquin County Development Title. Where no noise limits are specified for construction noise, a significant noise impact can be defined as interference with human activities during the day and night. One indicator that construction noise could interfere with daytime activities would be speech interference, and an indicator that construction noise could interfere with nighttime activities would be sleep interference. Nighttime is defined as activities taking place between 10:00 p.m. and 7:00 a.m.

Speech interference is an indicator of impact on typical daytime and evening activities. A speech interference criterion, in the context of impact duration and time of day, is used to identify a significant noise impact from temporary construction activities. Noise peaks generated by construction equipment could result in speech interference in adjacent buildings if the noise level in the interior of the building exceeds 45 to 60 dBA.[1] A typical building can reduce noise levels by 25 dBA with the windows closed (U.S. EPA, 1974). This noise reduction could be maintained only on a temporary basis in some cases, since it assumes windows must remain closed at all times. Assuming a 25-dBA reduction with the windows closed, an exterior noise level of 70 dBA L_{eq} at receptors would maintain an acceptable daytime interior noise environment of 45 dBA. It should be noted that such noise levels would be sporadic rather than continuous, because different types of construction equipment would be used throughout the construction process.

Noise peaks generated by construction at night could result in sleep interference in adjacent buildings if the noise level in the interior exceeds an interior level of 35 dBA (U.S. EPA, 1974). Assuming a 25-dBA reduction with the windows closed used for the speech interference criterion, an exterior noise level of 60 dBA L_{eq} at receptors would maintain an acceptable interior nighttime noise environment.

Transportation Noise

The County Development Title specifies L_{dn} limits for transportation noise sources. These limits would apply to the traffic associated with construction activities at both sites. The standard applicable to residential land uses is an L_{dn} of 65 dBA (San Joaquin Development Title, Table 9-1025.9, Part I).

Operational Noise

The County Development Title specifies L_{eq} limits for stationary noise sources. These limits would apply to the water treatment equipment that would be installed at the Tesla Portal and Thomas Shaft sites under the proposed project. Table 4.10-5 identifies the County's maximum allowable noise exposure from a stationary source.

[1] For indoor noise environments, the highest noise level that permits relaxed conversation with 100 percent intelligibility throughout the room is 45 dBA. Speech interference is considered to become intolerable when normal conversation is precluded at 3 feet, which occurs when background noise levels exceed 60 dBA. For outdoor environments, the highest noise level that permits normal conversation at 3 feet with 95 percent sentence intelligibility is 66 dBA (U.S. EPA, 1974).

TABLE 4.10-5
SAN JOAQUIN COUNTY MAXIMUM ALLOWABLE NOISE EXPOSURE – STATIONARY NOISE SOURCES

	Outdoor Activity Areas Daytime (7:00 A.M. to 10:00 P.M.)[1,2]	Outdoor Activity Areas Nighttime (10 P.M. to 7:00 A.M.)[1,2]
Hourly Equivalent Sound Level (L_{eq}), dBA	50	45
Maximum Sound Level (L_{max}), dBA	70	65

Notes:
1. Where the location of outdoor activity areas is unknown or is not applicable, the noise standard shall be applied at the property line of the receiving land use. When determining the effectiveness of noise mitigation measures, the standards shall be applied on the receiving side of noise barriers or other property line noise mitigation measures.
2. Each of the noise level standards specified shall be reduced by 5 dBA for impulsive noise, single tone noise, or noise consisting primarily of speech or music.

Source: San Joaquin County Development Title, Table 9-1025.9, Part II.

Occupational Noise Standards

Federal Occupational Safety and Health Administration

Under the Occupational Safety and Health Act of 1970 (29 USC Section 1919 et seq.), the Federal Occupational Safety and Health Administration (OSHA) has adopted regulations designed to protect workers against the effects of occupational noise exposure. These regulations list permissible noise level exposure as a function of the amount of time during which the worker is exposed. The noise exposure level of workers is regulated at 90 dBA over an 8-hour work shift (29 Code of Federal Regulations 1910.95); higher levels are permissible for shorter periods of time. If employees are exposed to levels exceeding 85 dBA for 8 hours, employers must develop a hearing conservation program. Such programs include monitoring the noise to which workers are exposed, making workers aware of overexposure to noise, and periodically testing the workers' hearing to detect hearing loss.

California Occupational Safety and Health Administration

Occupational noise exposure is regulated by California Occupational Safety and Health Administration (Cal-OSHA), which has promulgated Occupational Noise Exposure Regulations (California Code of Regulations, Title 8, Sections 5095-5099). These regulations set employee noise exposure limits and are equivalent to the Federal OSHA standards described above.

Vibration

The FTA has identified criteria for assessing the impacts of ground-borne vibration associated with rail and transit construction projects, which have been applied by other jurisdictions to other types of projects. The FTA measure of the threshold for architectural damage for sensitive structures is 0.2 in/sec PPV. The threshold of perception is 0.01 in/sec PPV (U.S. Department of Transportation, Federal Transit Administration, 2006).

The NPS has published guidelines for assessing the impact of vibration on historic structures (NPS, 1984). The NPS measure is 0.2 in/sec PPV for historic or architectural structures and 0.5 in/sec PPV for all other historic sites.

4.10.3 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to noise, but generally considers that implementation of the proposed project would have a significant noise impact if it were to:

- Expose people to or generate noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies
- Expose people to or generate excessive groundborne vibration or groundborne noise levels
- Create a substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project
- Create a substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project
- For a project located within an area covered by an airport land use plan (or, where such a plan has not been adopted, within two miles of a public airport or public use airport), expose people residing or working in the project area to excessive noise levels
- For a project within the vicinity of a private airstrip, expose people residing or working in the project area to excessive noise levels
- Be substantially affected by existing noise levels

For this project, potential significant impacts were evaluated using the following standards from the San Joaquin Development Title, Section 9:

- Proposed project construction activities would create unacceptable (70 dBA L_{eq} daytime, 60 dBA L_{eq} nighttime) short-term sound levels at noise-sensitive receptors.
- Proposed project generated traffic would result in sound levels exceeding 65 dBA L_{dn} at residential land uses as recommended in the San Joaquin County Development Title
- Stationary sources would result in noise levels at sensitive receptors exceeding hourly levels of 50 dBA L_{eq} (daytime) or 45 dBA L_{eq} (nighttime)
- Proposed project-generated vibration would exceed 0.2 in/sec PPV at sensitive structures

Areas of No Project Impact

Several of the criteria listed above are *not applicable* to the proposed project, as there either is no potential for the impact to occur, or the applicable environmental resource does not occur within the study area or the area of potential effect. As discussed above, neither site is located within two miles of a public airport or public use airport or is in an area covered by an airport land use plan, and neither site is located in the vicinity of a private airstrip. In addition, the noise sources in the vicinity of project sites would have no impact upon project construction or operation. The project sites are primarily used as water treatment facilities, which are not considered sensitive receptors. Implementation of the proposed project would not alter land uses adjacent to the project site. Project construction at the Thomas Shaft site would not require soil hauling, as no grading would be needed and vehicle trips are estimated to be low during both the six-month construction period; therefore, no impacts to sensitive receptors from noise along construction truck routes would occur. Also at the Thomas Shaft site, given the types of equipment that would be used and the distance to the nearest sensitive receptors, vibration impacts to offsite receptors would be less than 0.2 in/sec PPV from activities and, thus, the project would not cause disturbances due to construction-related vibrations. Therefore, the proposed project would have no impact with respect to these significance criteria.

Approach to Analysis

This analysis assesses potential noise and vibration impacts from construction activities, construction traffic, and operations of the proposed project. For construction noise and vibration, the potential for impact is defined by the proximity of sensitive receptors, typical noise and vibration levels associated with construction equipment, the potential for construction noise levels to interfere with daytime and nighttime activities, whether construction noise audible to nearby receptors will occur outside of construction time limits specified in local ordinances, or whether vibration levels are expected to exceed 0.2 in/sec PPV at sensitive structures. For operational noise, the potential for impact is defined by the proximity of sensitive receptors to the proposed facilities, and the potential for operational noise to remain within noise ordinance limits at the nearest receptors.

Construction Impacts

Impact 4.10-1: Disturbance from temporary construction-related noise increases (Tesla Portal: PSM; Thomas Shaft: LS)

Construction activities associated with the project would result in a short-term, temporary increase in the ambient noise level. Noise would result from operation of the construction equipment. The increase in noise level would be primarily experienced close to the noise source. The magnitude of the impact would depend on the type of construction activity, noise level generated by various pieces of construction equipment, duration of the construction phase, and distance between the noise source and receiver. Table 4.10-6 shows maximum noise levels generated by typical construction equipment. Sound levels of typical construction equipment range from approximately 65 dBA to 95 dBA at 50 feet from the source, with an average level of 89 dBA at 50 feet during the noisiest activities (U.S. Environmental Protection Agency [U.S. EPA], 1971). This analysis will use 89 dBA at 50 feet as the reference noise level for construction noise for both daytime and nighttime noise.

Acoustical calculations were performed to estimate noise from construction activities at the closest residences. Noise from the activity was assumed to have point source acoustical characteristics. Generally, a point source sound diminishes at a rate of 6 dB per doubling of distance from the source. This is a logarithmic relationship that does not take into account the type of ground surface the sound travels over. The calculations are based on the formula below (Harris, 1998):

$$SPL_2 = SPL_1 - 20\log\left(\frac{d_2}{d_1}\right), \text{ where:}$$

SPL_1 = known sound level,

SPL_2 = desired sound level,

d_1 = known distance, and

d_2 = desired distance.

TABLE 4.10-6
TYPICAL NOISE LEVELS AND ABATEMENT POTENTIAL OF CONSTRUCTION EQUIPMENT NOISE AT 50 FEET (IN dBA)

	Noise Level at 50 Feet		Expected Equipment at Each Site[b]

[a] Estimated levels can be obtained by selecting quieter procedures or machines and implementing noise-control features that do not require major redesign or extreme cost (e.g., improved mufflers, equipment redesign, use of silencers, shields, shrouds, ducts and engine enclosures).
[b] All equipment could be used during either day or nighttime work.

Source: U.S. Environmental Protection Agency, 1971; U.S. Department of Transportation, Federal Transit Administration, 2006

SFPUC Standard Construction Measure #6 for noise requires compliance with local noise ordinances regulating construction to the extent feasible.

Most construction activities from the project would not occur between 9:00 p.m. and 6:00 a.m. which is in accordance with the San Joaquin County noise ordinance construction time limits. However, some activities could occur at night, particularly during the tie-ins, as described in Section 3.3.1.

Tesla Portal Site

Apart from the movement of construction materials, construction activities for the proposed project would take place within the boundaries of the Tesla Portal site.

Typical noise levels for these equipment types can be found in Table 4.10-6.

Offsite Sensitive Receptors: The offsite noise-sensitive receptors in the vicinity of the Tesla Portal site consist of the residential community of Chrisman approximately 0.75 mile to the east, a residence approximately 2,500 feet to the southeast, and several uninhabited ranch structures approximately 750 feet to the west. Based on the distance from the proposed construction activities, resulting hourly sound levels at the community of Chrisman and the residence to the southeast would average approximately 55 dBA and levels at the ranch structures to the west would be approximately 65 dBA. Because of the intermittent nature of construction work, the energy average sound level for an 8-hour workday would be expected to be substantially less than predicted.

The estimated noise levels at the residences would be below the daytime speech interference criterion of 70 dBA and the nighttime sleep interference criterion of 60 dBA; therefore, there would be a less-than-significant impact for offsite sensitive receptors. Estimated noise levels at the ranch structures would exceed the sleep interference criterion; however, impacts would be less-than-significant because they are uninhabited. Moreover, actual noise levels at the receptors would be less than predicted with the implementation of SFPUC Standard Construction Measure #6 that requires contractors to undertake efforts to minimize any noise disruption to nearby neighbors and sensitive receptors during construction.

Onsite Sensitive Receptors: Even with the incorporation of noise reduction techniques on equipment, noise levels would often be above the speech and sleep interference criteria at the caretaker's residence at Tesla Portal. Given the proximity of the caretaker's residence to the proposed construction areas at Tesla Portal, construction-related noise would likely be beyond what is acceptable and, therefore, would be a potentially significant impact. Mitigation Measure 4.10-1, which requires this residence be vacated during construction activities that would exceed the speech and sleep interference criteria, would reduce potentially significant noise impacts to a less-than-significant level.

Noise levels generated by individual pieces of equipment, including those with noise controls, could exceed OSHA and Cal-OSHA standards for workers in the immediate vicinities of such equipment. Compliance with regulatory standards would ensure that workers would be adequately protected from potential noise hazards. For example, areas with decibel levels above 85 dBA would be posted as high-noise level areas, and hearing protection would be required.

Thomas Shaft Site

Apart from the movement of construction materials, construction activities at the Thomas Shaft site would be within site boundaries. Fewer types of construction equipment would be required for construction at the Thomas Shaft site than the equipment listed above for construction at the Tesla Portal site, and the construction period would be limited to six months, compared to the two-year construction period at the Tesla Portal site.

Typical noise levels for this equipment are found in Table 4.10-6. The only sensitive receptor in the immediate vicinity of the Thomas Shaft site is a rural residence located about 1.25 miles to the northeast of the Thomas Shaft site. Based on the distance from the proposed construction activities, sound levels at the residence to the northeast would be 47 dBA. This estimated level would be below the daytime speech interference criterion and the nighttime sleep interference criterion. Furthermore, because the Thomas Shaft site is separated by hills from the sensitive receptor, noise generated by construction activities would likely not be audible. Therefore, construction noise is considered to be less than significant.

No employees are stationed at the Thomas Shaft site. Regarding construction workers, similar considerations would apply to occupational noise as discussed above for the Tesla Portal site, therefore, the impact is considered to be less than significant.

Impact 4.10-2: Temporary noise disturbance along construction haul routes (Tesla Portal: LS; Thomas Shaft: LS)

Construction-related vehicle trips that would occur as a result of the proposed project would include construction workers traveling to and from the project sites, and materials and equipment deliveries. Truck noise is the major potential contributor to noise impacts along haul routes. A traffic analysis was conducted to determine the potential traffic impacts on the local circulatory system due to the project (see Section 4.8, Traffic, Transportation and Circulation). The Federal Highway Administration (FHWA) Traffic Noise Model Version 2.5 Look-Up is a Windows-based program that calculates highway traffic noise for an infinitely long, straight roadway over flat ground, with a receiver set at a height of 5 feet above the ground. This program was used to calculate existing and existing with project noise levels at 50 feet from the centerline of the roadways for the purpose of estimating the change in sound level resulting from the project at offsite receptors.

Calculations were performed for a distance of 50 feet from I-580, SR 32, West Vernalis Road, South Chrisman Road, Corral Hollow Road, and Thomas Shaft Road. The actual sound level at receptor locations is dependent on such factors as the source-receptor distance and the presence of intervening structures, barriers, and topography. The modeling effort considered estimated average vehicle speed and the average daily traffic (ADT). The following assumptions were included in the model for existing conditions: (1) peak hour traffic volume is 10 percent of the ADT; (2) truck mix of 16 percent for I-580, 25 percent for SR 32, and 5 percent for all other roads; and (3) average speeds of 65 miles per hour (mph) on I-580, 55 mph on SR 32, and 35 mph on all other roads. The following assumptions were included in the model for project-generated traffic: (1) approximately 65 percent of the ADT was heavy trucks; (2) trucks would operate between 6:00 a.m. and 9:00 p.m.; (3) trucks would be evenly distributed over the 15-hour period; and (4) average speeds were the same as for existing conditions.

The model also assumed "hard" site propagation conditions, i.e., a paved surface such as roadways, parking lots, or hard-packed graded lots. Generally, a hard site propagation rule diminishes traffic sound from a source to a receiver at a rate of 3 dB per doubling of distance from the source. This is a logarithmic relationship that applies to the propagation of sound waves with no ground interaction or the interaction with a hard surface.

Tesla Portal Site

The access route for the Tesla Portal site includes I-580, Chrisman Road, and West Vernalis Road. As discussed in Section 4.8, Traffic, Transportation and Circulation, construction activities would result in a temporary addition of 25-30 roundtrips (50 to 60 daily construction trips) for approximately 24 months. The single-day peak number of construction trips, including estimated daily construction and single-day concrete delivery, would be 340 trips (170 round trips) on concrete pouring days. Calculations were performed for both average and peak construction trip scenarios. Table 4.10-7 summarizes the results of the calculations. A review of the table shows that sound levels would increase by less than 1 dBA on I-580 and SR 132 by 7 dBA on West Vernalis Road, and by 4 dBA on South Chrisman Road with peak trips and by less than 3 dBA for all roadways with average construction trips.

Table 4.10-7 shows that calculated sound levels with and without the project along all roadways except I-580 and SR 132 would remain below the 65 dBA community noise equivalent level (CNEL) threshold at residential uses. The table also shows that sound levels would increase by less than 1 dBA along I-580 or SR 132, which would be imperceptible. Additionally, SFPUC Standard Construction Measure #6 for noise would be applied. Therefore, impacts to residences along these roadways are considered less than significant.

TABLE 4.10-7
CALCULATED TRAFFIC SOUND LEVELS AT 50 FEET FROM ROADWAYS (DBA CNEL)

Roadway	Existing		With Project (Peak Trips)[1]			With Project (Average Trips)[2]		
	ADT[3]	Calculated Level (dBA CNEL)[4]	ADT	Calculated Level (dBA CNEL)	Delta	ADT	Calculated Level (dBA CNEL)	Delta
Tesla Portal Site								
Interstate 580	31550	80.7	31890	80.8	0.10	31610	80.7	0.0
State Route 32	19500	77.8	19840	77.9	0.10	19560	77.8	0.0
West Vernalis Road	400	52.6	740	59.3	6.70	460	54.8	2.2
South Chrisman Rd	1140	57.1	1480	60.7	3.60	1200	58.0	0.9
Thomas Shaft Site								
Corral Hollow Road	3474	62.0	3486	62.0	0.00	3476	62.0	0.0
Thomas Shaft Road	11	36.8	23	44.3	7.50	13	39.5	2.7

[1] Peak trips based on 170 roundtrips (340 trips) per day for Tesla Portal site and 5 roundtrips (10 trips) per day for Thomas Shaft site
[2] Average trips based on 30 roundtrips (60 trips) per day for Tesla Portal site and 2 trips per day for Thomas Shaft site
[3] ADT = Average daily traffic
[4] dBA CNEL = A-weighted decibel, community noise equivalent level
[5] Delta is difference between with project ADT (average and peak trips) and existing ADT

Thomas Shaft Site

The access route for the Thomas Shaft site includes Corral Hollow Road and Thomas Shaft Road. As discussed in Section 4.8, construction activities would result in a temporary addition of two daily construction trips for approximately 6 months. The single-day peak number of construction trips would be 10 trips on concrete pouring days. Calculations were performed for both average and peak construction trip scenarios. Table 4.10-7 summarizes the results of the calculations. A review of the table shows that sound levels along all roadways would not increase on Corral Hollow Road for peak or average trips, and would increase by 3 dBA or 8 dBA for average or peak trips, respectively, on Thomas Shaft Road. However, because there are no residences on Thomas Shaft Road, impacts are considered less than significant.

Table 4.10-7 shows that calculated sound levels with and without the project along all roadways would remain below the 65 dBA CNEL threshold at residential uses on Corral Hollow Road. In addition, SFPUC Standard Construction Measure #6 would be implemented. Therefore, impacts to residences along this roadway are considered less than significant.

Impact 4.10-3: Disturbance due to construction-related vibration (Tesla Portal: PSM; Thomas Shaft: N/A)

Some construction equipment can cause vibration that could disturb local residents and cause cosmetic damage to buildings and structures. Therefore, vibration from equipment proposed for this project was analyzed to determine the potential impact to neighbors and structures.

Table 4.10-8 presents the vibration levels generated by different types of construction equipment. The highest level of vibration for proposed construction is generated by large bulldozers, which generate approximately 87 VdB or 0.089 in/sec PPV. This level was used to estimate vibration levels at sensitive receptors. Vibration propagates according to the following expression, based on point sources with normal propagation conditions (U.S. Department of Transportation, Federal Transit Administration, 2006):

$$PPV_{equip} = PPV_{ref}\left(\frac{D_{ref}}{D}\right)^{1.5}$$

where: PPV_{equip} = the peak particle velocity in in/sec of the equipment adjusted for distance
PPV_{ref} = the reference vibration level in in/sec at 25 feet
D_{ref} = the reference distance
D = the distance from the equipment to the receiver

TABLE 4.10-8
VIBRATION LEVELS FOR CONSTRUCTION EQUIPMENT AT 25 FEET

Equipment[a]	PPV at 25 Feet (in/sec)	VdB at 25 feet
Large Bulldozer	0.089	87
Loaded Trucks	0.076	86
Jackhammer	0.035	79
Small Bulldozer	0.003	58

Notes: Vibration levels for construction equipment at 25 feet are based on measured data near various types of equipment and assume normal propagation conditions.

It should be noted that vibration propagation characteristics would depend on a number of factors, including the type and condition of geologic materials, depth of construction, and type of construction equipment and activity.

Source: U.S. Department of Transportation Federal Transit Administration, 2006.

Tesla Portal Site

Based on an upper limit vibration level of 0.089 in/sec at 25 feet from a large bulldozer and the general FTA vibration propagation formula given above, at the closest offsite sensitive receptors (uninhabited ranch structures) at 750 feet, the equipment would generate a velocity level of less than 50 VdB or a PPV of 0.00054 in/sec. At the onsite caretaker's residence (40 feet from equipment), the vibration levels would be 0.044 in/sec PPV and 55 VdB. The vibration level is acceptable for both humans and structures; therefore impacts are considered to be less than significant.

As discussed in Section 4.7, Cultural Resources, the Southwest Valve House and the portions of the San Joaquin Pipelines 1 and 2 located at the Tesla Portal site would be eligible for listing on

the National Register of Historic Places and the California Register of Historic Resources. Construction activities at the Tesla Portal site would take place approximately 25 feet from the Southwest Valve House. Based on an upper vibration level of 0.089 in/sec at 25 feet from a large bulldozer, which is below the 0.2 in/sec PPV threshold for sensitive structures, impacts would be less than significant.

As described in Section 3.3.1, the tie-in of the proposed UV Building to San Joaquin Pipelines 1 and 2 would require cutting into pipelines and connecting a new manifold. Due to the proximity of the construction activity, vibration levels are expected to exceed the 0.2 in/sec threshold for sensitive structures and, therefore, would be a potentially significant impact. Mitigation Measure 4.10-2, which requires the construction contractor to conduct work in a manner that maintains the structural integrity of the pipelines, would reduce potentially significant vibration impacts to a less-than-significant level.

Operational Impacts

Impact 4.10-4: Disturbance due to long-term noise increases associated with operation of project facilities (Tesla Portal: LS; Thomas Shaft: LS)

Tesla Portal Site

Operational noise at Tesla Portal would consist of noise generated by the addition of up to two diesel standby power generators. The proposed generators would be used infrequently, and only during power outages and for periodic testing, which would be conducted during daytime hours. Although the new UV equipment would operate 24 hours/day, the equipment would be located within the proposed UV building and would not be audible outside of the building. Due to the distance to the offsite sensitive receptors, noise from these sources would be below the San Joaquin County noise limit of 50 dBA L_{eq}, and would not represent a substantial increase in the ambient noise level at the site. Therefore, impacts would be less than significant.

Thomas Shaft Site

Thomas Shaft is not located near any noise-sensitive land uses, and potential operational noise from the proposed UV reactors would be negligible given that they would be enclosed within the existing Chlorination Facility building. The two new pumps would be installed 300 feet below ground and would not be audible at the ground surface. Therefore, operational noise associated with the proposed facilities would be less than significant.

4.11 Public Services and Utilities

4.11.1 Setting

Water Service

The San Francisco Public Utilities Commission (SFPUC) provides water delivery services to retail and wholesale customers, primarily in San Francisco, San Mateo, Santa Clara, and Alameda counties, as well as isolated regional retail customers along the water system. The SFPUC currently provides potable water to the Tesla Portal site. No potable water is currently supplied to the Thomas Shaft site, but there is a 5,000-gallon water tank and pump for fire protection.

SFPUC has a contractual agreement with Lawrence Livermore National Laboratory (LLNL), one of the SFPUC's retail customers, to deliver drinking water to LLNL Site 200 from Mocho Shaft and to LLNL Site 300 from Thomas Shaft, under which the maximum rate of flow contracted will not exceed 0.8 million gallons per day (mgd). To assist in water delivery to Site 300, LLNL installed a ten-inch water line and pumps in 1995 across Thomas Shaft Road from the existing Chlorination Facility. However, currently, the SFPUC supplies LLNL only from Mocho Shaft because water from Thomas Shaft does not meet the Surface Water Treatment Rule (SWTR) for *Giardia* inactivation. The current water supply for Site 300 comes from onsite wells[1] serving a population of about 250 workers and visitors.

Law Enforcement Services

The San Joaquin County Sheriff's Department provides law enforcement services within San Joaquin County, including the Tesla Portal and Thomas Shaft sites. The Sheriff's Department is headquartered in French Camp, approximately five miles south of Stockton. The Sheriff's Department serves approximately 138,400 people in unincorporated San Joaquin County and has approximately 815 permanent positions. The County is generally a low-crime area with the most common crimes being thefts and burglaries (San Joaquin County Sheriff's Department, 2007b).

Fire Protection Services

The City of Tracy Fire Department provides both fire protection and emergency medical services to the project sites. The Fire Department employs 60 professional firefighters and approximately 30 reserve firefighters and maintains eight fire stations, two of which are located near the project sites at 7700 Linne Road (Station 95) and 1551 Durham Ferry Road (Station 93).

---

1 The wells are owned by the Department of Energy/National Nuclear Security Administration, and operated by Lawrence Livermore National Security, LLC (LLNS), the contractor in charge of LLNL. LLNS is a limited liability corporation made up of Bechtel National, Inc., the University of California, BWX Technologies, Inc., and the Washington Group International, Inc. The team also includes Battelle Memorial Institute, four small business subcontractors, and Texas A&M University.

Station 95, which is approximately four miles from the Tesla Portal site and eight miles from the Thomas Shaft site, currently serve the project site and would continue to do so in the future. Station 95 has a 1984 Van Pelt 1,500 gallons per minute (gpm) Type 1 Pumper and 2000 Ford F-550 Type 4 Pumper in reserve status. Type I fire engines are designed to protect structures, with the ability to pump 1,250 gpm. Type IV fire engines are designed to fight wildfires, and carry 400 gallons of water and 20 gallons of wildland firefighting foam (City of Tracy Fire Department, 2007).

Station 93, located at 1551 Durham Ferry Road in New Jerusalem, is approximately 5 ½ miles from the Tesla Portal site and 10 miles from the Thomas Shaft site. Station 93 houses a 1997 American La France/High Tech (Engine 93) (City of Tracy Fire Department, 2007).

Solid Waste Management

Solid waste in San Joaquin County is taken by collection agencies and individuals either directly to landfills or to transfer stations, which accumulate waste for later transport to landfills. There are three active landfills within San Joaquin County: Foothill Sanitary Landfill, Forward Landfill, Inc., and North County Landfill. The closest landfill to the project sites is the Forward Landfill, located on Waverly Road. The Forward Landfill opened in 1973 and has a total capacity of 51,040,000 cubic yards of waste. With 78.4 percent capacity remaining, it is not scheduled to close until the year 2020 (CIWMB, 2007a). Table 4.11-1 identifies active landfills in San Joaquin County and the types of waste they accept.

Wastewater

Wastewater is collected, treated, and disposed of in San Joaquin County in two ways: community collection and treatment systems and individual onsite treatment systems (San Joaquin County General Plan, 2007). Septic tank systems are the major means of onsite wastewater treatment and disposal in rural areas of San Joaquin County. Septic tanks are onsite systems that receive wastewater, allow heavier solids to settle in a tank, and release the remainder of the effluent to leach fields. The leach fields consist of perforated lines through which the wastewater percolates into the soil. The remaining solids must be periodically pumped from the tank and disposed. There is an existing septic tank and leachfield serving onsite structures at the Tesla Portal site; there are no wastewater disposal facilities at the Thomas Shaft site (there are no restroom facilities onsite).

TABLE 4.11-1
ACTIVE LANDFILLS WITHIN SAN JOAQUIN VALLEY

Active Landfills	Total Estimated Permitted Capacity[a] (cubic yards)	Remaining Estimated Capacity (cubic yards)	Remaining Capacity Date[b]	% Remaining Capacity	Closure Date	Waste Types Accepted/Permitted
Foothill Sanitary Landfill	102,000,000	94,969,466	As of 6/1/2005	93.1%	1/1/2054	Agricultural, construction/ demolition, industrial, mixed municipal, tires, wood waste
Forward Landfill, Inc.	51,040,000	40,031,058	As of 1/1/2002	78.4%	1/1/2020	Agricultural, asbestos, asbestos friable, ash, construction/demolition, contaminated soil, green materials, industrial, mixed municipal, sludge (biosolids), tires, shreds
North County Landfill	17,300,000	13,239,032	As of 9/1/2004	76.5%	1/1/2035	Agricultural, construction/ demolition, industrial, metals, mixed municipal, other designated, tires, wood waste

a Capacity information from 2000 (California Integrated Waste Management Board [CIWMB], 2007b)
b Calculated using CIWMB, 2007 data.

Stormwater

Stormwater at the Tesla Portal site drains off of the paved surfaces to the adjacent open fields. In addition, the site contains an artificial wetland area as well as a small-unnamed ephemeral drainage feature. The wetland area is approximately 0.308 acre in size and was created in upland habitat from the release of untreated sample water from the existing Tesla Portal facilities. The ephemeral drainage is located in the southern border of the site and is approximately 1.5 feet wide. The ephemeral drainage is a product of rainfall in the nearby hills and it is also used as a drainage outlet for emergency releases from an SFPUC overflow shaft. The overflow shaft releases overflow water from the Coast Range Tunnel at elevation 501 feet into a concrete spillway that drains to the ephemeral drainage.

At the Thomas Shaft site, surface runoff currently drains to the open areas on the site adjacent to paved surfaces.

Electricity

The SFPUC Power Enterprise provides electric power services for SFPUC facilities, primarily from power generation by the SFPUC's hydroelectric facilities in the Hetch Hetchy system. Some SFPUC sites, including both Tesla Portal and Thomas Shaft sites, are served and metered by Pacific Gas and Electric through their local distribution line using power from the Hetch Hetchy system. The Hetch Hetchy system comprises 400 megawatts of hydroelectric power generation plants on the Tuolumne River and 150 miles of high-voltage transmission lines linking Hetch Hetchy power to California's electricity grid at Newark. Energy production is discussed in greater detail in Section 4.14, Energy Resources.

Telecommunications

Telephone service is provided by AT&T in San Joaquin County via overhead and underground lines. Telephone service at the Tesla Portal site is provided by AT&T and telephone service at the Thomas Shaft site is provided by LLNL.

4.11.2 Regulatory Framework

California Public Utilities Commission

The California Constitution vests in the California Public Utilities Commission (CPUC) exclusive power and sole authority with respect to the regulation of privately-owned and investor-owned public utilities. This exclusive power extends to all aspects of the location, design, construction, maintenance, and operation of regulated utility facilities. The CPUC has provisions for regulated utilities to work closely with local governments and give due consideration to their concerns.

California Integrated Waste Management Act of 1989

- The California Integrated Waste Management (CIWM) Act of 1989 (Public Resources Code [PRC], Division 30), enacted through Assembly Bill (AB) 939 and modified by subsequent legislation, requires all California cities and counties to implement programs to reduce, recycle, and compost at least 50 percent of wastes by the year 2000 (PRC Section 41780). The state determines compliance with this mandate (which includes both disposed and diverted waste) through a complex formula. This formula requires cities and counties to conduct empirical studies to establish a "base year" waste generation rate against which future diversion is measured. The actual determination of the diversion rate in subsequent years is arrived at through deduction, not direct measurement. Instead of counting the amount of material recycled and composted, the city or county tracks the amount of material disposed at landfills, then subtracts the disposed amount from the base year amount. The difference is assumed to be diverted (PRC Section 41780.2).

In the original determination of their base year generation rate, cities and counties may not count certain diverted materials, including agricultural wastes, scrap metals, discarded major appliances, or inert solids such as rock, concrete, brick, sand, soil, fines, asphalt, and unsorted

construction and demolition waste, unless the city or county can demonstrate that these materials had previously been disposed in a landfill and were now being diverted through a specific action of the city or county (PRC Section 41781.2). In subsequent years, these materials only have an impact on a city's or county's attainment of the diversion mandate if the materials are disposed in landfills. If they continue to be diverted, they are never accounted for.

4.11.3 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to public services and utilities, but generally considers that implementation of a proposed project would have a significant impact if it were to:

- Result in substantial adverse physical impacts associated with the provision of, or the need for, new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for any public services such as fire protection, police protection, schools, parks, or other services

- Exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board (RWQCB)

- Require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects

- Require or result in the construction of new stormwater drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects (discussed in Section 4.5)

- Not have sufficient water supply available to serve the project from existing entitlements and resources, or require new or expanded water supply resources or entitlements

- Result in a determination by the wastewater treatment provider that would serve the project that it has inadequate capacity to serve the project's projected demand in addition to the provider's existing commitments

- Be served by a landfill with insufficient permitted capacity to accommodate the project's solid waste disposal needs

- Be out of compliance with federal, state, and local statutes and regulations related to solid waste

- Disrupt operation of or require relocation of regional or local utilities

Areas of No Project Impact

Under some of the significance criteria listed above, there is no potential for the impact to occur with implementation of the proposed project, or the criterion is not applicable to the proposed project, as the applicable environmental resource does not occur within the project area. The project would not increase local population, or otherwise affect the need for fire protection, police protection, schools, parks or other public services.

At the Thomas Shaft site, solid waste generation would be minimal and would occur during the six-month construction period. No demolition is proposed that would generate construction waste, and soil excavation associated with the 150 feet by 3 feet by 3 feet trench between the existing Chlorination Facility building and the Thomas Shaft would be roughly balanced onsite. During project operation, similar to existing conditions, there would be no permanent onsite employees at Thomas Shaft site. Therefore, solid waste generation during construction and operation would not adversely affect landfill capacity in San Joaquin County, nor would it violate any federal, state or local statutes and regulations related to solid waste. There would be no impact with respect to the significance criteria related to solid waste at the Thomas Shaft site.

During project operation, the increase in the number of onsite employees would be minimal (two new employees at the Tesla Portal site and no new employees at the Thomas Shaft site), and the associated increase in the demand for potable water and the generation of wastewater or solid waste would also be minimal. At the Tesla Portal site, wastewater is treated by onsite wastewater treatment/disposal facilities (septic tank and leachfield), and the site is not served by an offsite municipal treatment facility. The project would construct a new septic tank and leachfield at the Tesla Portal site to serve the proposed building, in compliance with applicable individual sewage disposal system permitting requirements described in the San Joaquin County Environmental Health Department's Onsite Wastewater Disposal Standards (San Joaquin County, 2003), and would not discharge wastewater offsite from the Tesla Portal site. No wastewater facilities are proposed at the Thomas Shaft site. At the Tesla Portal site, project operation would not substantially increase water demand because the proposed improvements would result in only three new employees, and the minimal increase in demand would be accommodated by existing onsite systems. No potable water is currently supplied to the Thomas Shaft site, and is not proposed as part of the project. Therefore, project operation would not result in an insufficient water supply at either site.

Project operation would result in a minimal increase in the number of employees as the Tesla Portal site, and no increase at the Thomas Shaft site. The associated incremental increase in solid waste generation would be accommodated by existing services, and would comply with federal, state and local statutes and regulations and would be served by nearby landfills with adequate capacity.

Project operation would not contribute stormwater to any offsite storm drainage facilities, nor would it require the construction of new storm drainage facilities or the expansion of such facilities at either of the project sites. Additionally, the project would not result in service

disruption or relocation of subsurface or above ground utility lines or cables. Therefore, project operation would not result in impacts associated with these significance criteria, and project operational impacts are not discussed further.

Approach to Analysis

One area of focus of this analysis is on temporary construction-related impacts on utility services. Implementation of the project would not have direct, long-term impacts on the demand for public utilities, with the exception of electricity (discussed in Section 4.14, Energy Resources). Long-term electricity use would increase for the proposed project.

The second focus of this analysis is the potential temporary impact on landfill capacity due to the disposal of construction waste from the Tesla Portal site. The largest potential source of solid waste would be removed pipeline segments and asphalt from part of the access road that would be removed at the Tesla Portal site. This analysis assumes that excavated soil would be reused onsite and would not be disposed in landfills.

Construction Impacts

Impact 4.11-1: Potential temporary damage to or disruption of existing regional and local public utilities (Tesla Portal: LS; Thomas Shaft: LS)

The existing facilities at the Tesla Portal and Thomas Shaft sites would be upgraded and expanded to increase system reliability and improve the supply of water to SFPUC customers. These new facilities would be built within the SFPUC's existing property and would not affect offsite utility services. In addition, construction of new facilities at the Tesla Portal site would not interrupt service to existing water supply customers. The system would be shutdown during a regularly scheduled maintenance shutdown from approximately January 5, 2010, to February 16, 2010, which would allow for the tie-in to the new facilities at the Tesla Portal site. However, no interruption to SFPUC water customers would result, as they would continue to be served by other system sources. At the Thomas Shaft site, no on or offsite utilities would be affected. Therefore, potential impacts to existing regional and local public utilities would be less than significant.

Impact 4.11-2: Temporary adverse effects on solid waste landfill capacity (Tesla Portal: LS; Thomas Shaft: N/A)

Construction of the proposed project at the Tesla Portal site would generate solid waste during construction. Potential solid waste materials include construction debris, pipeline segments that would be removed and replaced, and asphalt from the existing access road. This would result in approximately 500 cubic yards of solid waste. Due to the relatively flat nature of the site, it is

expected that cut and fill volumes would be roughly balanced onsite, and the project would not require offsite soil hauling.

The three landfills within the project vicinity, Foothill Sanitary Landfill, Forward Landfill, Inc., and North County Landfill, are permitted to accept construction and demolition waste. As shown in Table 4.11-1, there is landfill capacity to accept the solid waste anticipated to be generated by the project.

In addition, the SFPUC has standard practices and waste management requirements that would be implemented during project construction. These requirements include, but are not limited to, the recovery, reuse and recycling of demolition and salvage materials (SFPUC, 2008). Given the minimal amount of solid waste that would be generated at the Tesla Portal site during construction, available capacity of nearby landfills, and SFPUC construction practices, impacts from the project on solid waste landfill capacity would be less than significant.

Impact 4.11-3: Impacts related to compliance with federal, state and local statutes and regulations related to solid waste (Tesla Portal: LS; Thomas Shaft: N/A)

The proposed project would comply with all federal, state and local statutes and regulations related to solid waste. The CIWMB found that unincorporated San Joaquin County achieved a diversion rate of 59 percent for the year 2005 and, thus, is in compliance with the CIWM Act of 1989 (CIWMB, 2007b). Solid waste generated by the proposed project during construction would be minimal and is not expected to impact this diversion rate. Therefore, the impacts would be less than significant.

Operational Impacts

The proposed project would not result in operational impacts related to public services and utilities as described above.

4.12 Agricultural Resources

4.12.1 Setting

California leads the nation in agricultural production, responsible for approximately one-eighth of the country's agricultural output. San Joaquin County is among the top 15 most agriculturally productive counties in the state (California Legislative Analyst's Office, 2002; Umbach, 1997). San Joaquin County ranks among the top 10 counties in the state in terms of gross agricultural production value.

More than 45 percent of San Joaquin County's total land area (912,601 acres) consists of land designated as Prime Farmland. There is also substantial acreage designated as Farmland of Statewide Importance (10.1 percent), Unique Farmland (6.8 percent), Farmland of Local Importance (6.2 percent), and Grazing Land (16.3 percent). Almost 85 percent of the county is mapped as some type of important farmland (California Department of Conservation, 2005).

Both the Tesla Portal and Thomas Shaft sites are classified as Grazing Land by the maps prepared pursuant to the Farmland Mapping and Monitoring Program (San Joaquin County, 2007).

The project sites are located on extraterritorial land owned by the City and County of San Francisco (CCSF). California Government Code Section 53090 et seq. provides that CCSF receives intergovernmental immunity from the planning and building laws of any other city or county in which its extraterritorial lands are located. Therefore, the San Joaquin County zoning designation for the project sites is not binding, and is identified here for informational purposes. The San Joaquin County zoning designation for the project sites is AG-160 (General Agriculture). This zoning designation requires a minimum parcel size of 160 acres. The purpose of the AG zone is to preserve agricultural lands for the continuation of commercial agriculture enterprises. The following are permitted uses in the AG-160 zone:

- Single-family residential
- Group care facilities
- Small residential shelters
- Animal raising, including general animal raising, family food production, and educational animal projects
- Animal specialty services (farm)
- Family day care homes
- Crop production
- Farm produce stands

- Off-premises signs
- Minor utility services

In addition, this zoning designation allows a variety of other uses subject to site approval, or approval of an Improvement Plan, Quarry Excavation Permit, Second Dwelling Permit, or Use Permit. Specifically, germane to the proposed project, the AG-160 zone allows "essential" public services subject to site approval. While the Development Title of San Joaquin County specifies that lots zoned AG-160 must be at least 160 acres, it also allows AG-160 zoned parcels with an existing use or a use granted by a permit to be smaller than the required minimum size.

Additionally, both sites are within an agricultural preserve (R-69-C1). The R-69-C1 is a resolution that was passed by the San Joaquin County Board of Supervisors that allows properties with an agricultural land use designation to enter into a Williamson Act contract (Griffin, 2007).

The Tesla Portal and Thomas Shaft sites are located in rural settings with existing agricultural uses on adjacent lands consisting of ranching operations and cattle grazing. Neither the Tesla Portal site nor the Thomas Shaft site is under a Williamson Act contract. However, there is an existing grazing lease at the Tesla Portal site that allows cattle grazing.

4.12.2 Regulatory Framework

Land Conservation Act

The California Land Conservation Act (LCA), also known as the Williamson Act, was adopted initially by the state of California in 1965 with the basic intent of encouraging the preservation of the state's agricultural lands in view of the increasing trend toward their conversion to urban use. The LCA established a land contract procedure whereby a county board of supervisors could stabilize (i.e., not increase) taxes on certain qualifying lands in return for an owner's guarantee to keep the lands in agricultural preserve status for a ten-year period. A Williamson Act contract is automatically renewed each year, unless a notice of non-renewal is initiated by the land owner or the county. Once a notice of non-renewal is given, the contract remains in place on the land for the remaining nine-year term. Once the nine-year term expires, the land is no longer restricted to agricultural or open space uses. As of January 1, 2003, 16.6 million of the state's 30 million acres of farm and ranch land were protected by Williamson Act contracts.

Public Resources Code Section 21060.1

Public Resources Code Section 21060.1 defines agricultural land for the purposes of assessing environmental impacts using the Farmland Mapping and Monitoring Program (FMMP). The FMMP was established in 1982 to assess the location, quality, and quantity of agricultural lands and the conversion of these lands. The FMMP provides analysis of agricultural land use and land use changes throughout California.

The California Department of Conservation Farmland Mapping and Monitoring Program maps important farmlands throughout California. Important farmlands are divided into the following five categories based on their suitability for agriculture: Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Grazing Land. Prime Farmland is land with soils that have the best combination of physical and chemical characteristics for producing food, feed, forage, fiber, and oilseed crops. The land can be cropland, pastureland, rangeland, forestland, or other land, but not urban built-up land or water. Unique Farmland is used for specific high-value food and fiber crops. Farmland of Statewide Importance includes soils that are nearly prime, producing high yields of crops when treated and managed according to acceptable farming methods. Grazing Land is comprised of vegetation that is suited for the grazing of livestock.

4.12.3 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to agricultural resources, but generally considers that implementation of a proposed project would have significant impacts to these resources if it would:

- Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Department of Conservation, to a nonagricultural use
- Conflict with existing zoning for agricultural use, or a Williamson Act contract
- Involve other changes in the existing environment, which due to their location or nature, could result in conversion of Farmland of Statewide Importance to nonagricultural use

Approach to Analysis

For the purpose of this analysis, the project elements at both sites are considered in relation to farmland in the immediate vicinity of each site to identify any potential disruption that might be caused temporarily (during project construction) or permanently (due to project operations). In addition, the project was examined for its potential to affect land under Williamson Act contract.

Areas of No Project Impact

Under some of the significance criteria listed above, there is no potential for the impact to occur with implementation of the proposed project, or the criterion is not applicable to the proposed project, as the applicable environmental resource does not occur within the project area. Both the Tesla Portal and Thomas Shaft sites are designated as Grazing Land and, therefore, the project would not result in the conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural use. Moreover, the proposed improvements would not preclude agricultural activities on the portion of either site that is not developed with project

implementation. Neither project site is under a Williamson Act contract. Project construction or operation would not disrupt access or otherwise affect existing grazing operations on adjacent parcels. Therefore, the proposed project would have no impact with respect to these significance criteria.

Impact 4.12-1: Conflicts with existing zoning for agricultural use (Tesla Portal: LS; Thomas Shaft: LS)

The existing San Joaquin County zoning designation for both project sites is AG-160 (General Agriculture), the purpose of which is to preserve agricultural lands for the continuation of commercial agriculture enterprises. Both project sites contain facilities that are components of a regional water system (an essential public service) that is owned and operated by the CCSF. These essential public facilities are permitted in the AG-160 zone. The proposed project would replace and upgrade existing water treatment facilities at the Tesla Portal site, construct new water treatment facilities at the Tesla Portal site, and install an ultraviolet disinfection system at the Thomas Shaft site, as well as implement various ancillary improvements. These improvements would further the continued use of each site as an essential public facility, which is allowed under the agricultural zoning designation. Consequently, the proposed project would not conflict with the existing zoning for agricultural use.

Additionally, each site has contained regional water system facilities for more than 50 years. Therefore, even though both sites are smaller in size than the minimum required in the AG-160 zone, they are not in conflict with this requirement, as the Development Title of San Joaquin County allows AG-160 zoned parcels with an existing use to be smaller than the minimum acreage. Furthermore, there is an existing grazing lease at the Tesla Portal site, which is allowed under the AG-160 zoning designation. There is no grazing lease at the Thomas Shaft site.

Therefore, based on the discussion above, the proposed project would not conflict with existing zoning for agricultural uses and the impact would be less than significant.

4.13 Hazards

4.13.1 Setting

The Tesla Portal and Thomas Shaft sites are located in rural areas. Each facility stores hazardous materials on site, described later in this section. Neither project site is within 1/4 mile of an existing or proposed school (Merritt, 2007), nor is either site listed in the following databases that make up the lists compiled pursuant to Government Code Section 65962.5. Collectively, these lists are known as the Hazardous Waste and Substances Sites List, which is also known as the Cortese List (Cal EPA, 2007):

- List of Hazardous Waste and Substances sites from the Department of Toxic Substances Control EnviroStor database
- List of Leaking Underground Storage Tank Sites by County and Fiscal Year from the State Water Resources Control Board GeoTracker database
- List of solid waste disposal sites identified by the State Water Resources Control Board with waste constituents above hazardous waste levels outside the waste management unit
- List of "active" Cease and Desist Orders and Cleanup and Abatement Orders from the State Water Resources Control Board
- List of hazardous waste facilities subject to corrective action pursuant to Section 25187.5 of the Health and Safety Code, identified by Department of Toxic Substances Control

The closest Cortese List site to either the Tesla Portal or Thomas Shaft site is Lawrence Livermore National Laboratory (LLNL) Site 300, which is a National Priority List site. The boundary of the 11-square mile LLNL Site 300 is about 1.5 miles from the Thomas Shaft site, and approximately 4 miles from the Tesla Portal site. There is no evidence that groundwater or other contamination emanating from Site 300 has reached the Thomas Shaft site (LLNL, 2006), or the more distant Tesla Portal site.

Neither the Tesla Portal nor the Thomas Shaft sites are located within two miles of a public airport or in an area covered by an airport land use plan, and neither site is located in the vicinity of a private airstrip.

The Certified Unified Program Agency (CUPA) in San Joaquin County is the County Environmental Health Department.

Wildland Fire

The Tesla Portal and Thomas Shaft sites are in a “Moderate” Fire Hazard Severity Zone (San Joaquin County, 2007). Both project sites are in areas designated by the California Department of

Forestry and Fire Protection (CDF) as a "Wildland Area That May Contain Substantial Forest Fire Risks and Hazards" (CDF, 2000). The Tesla Portal site has adequate water supplies for fire-fighting and the Thomas Shaft site has an existing 5,000-gallon water tank with a pump for fire protection. See Section 4.11-1 for information on fire protection services at the sites.

Hazardous Materials

Tesla Portal Site

The Tesla Portal site has two 13,000-gallon and four 4,000-gallon aboveground storage tanks (ASTs) containing sodium hypochlorite, a liquid form of chlorine.[1] No chlorine gas is used, and no airborne releases of chlorine occur. Other hazardous materials at the Tesla Portal site include a 1,000-gallon propane AST, sodium thiosulfate, and small quantities of chemicals used for maintenance activities (paint thinner, oils, lubricants, isopropyl alcohol, transmission fluid, and antifreeze). The Tesla Portal site generates less than 55 gallons of hazardous waste per year, consisting of waste oil from machinery maintenance (CCSF 1999). A transformer at the Tesla Portal site was installed within the last few years and does not contain polychlorinated biphenyls (PCBs) (refer to "Hazardous Building Materials," later in this section).

A Phase I Environmental Site Assessment (ESA), including a site inspection and a review of environmental databases, was conducted for the Tesla Portal site by AGS, Inc. (AGS, 2007). The types of sites identified in the environmental databases include permitted hazardous materials uses,[2] environmental cases,[3] and spill sites.[4] AGS did not find any current or historical recognized environmental conditions at Tesla Portal site. As defined by ASTM E1527-05, *Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process*, recognized environmental conditions are the presence or likely presence of any hazardous substances or petroleum products on a property under conditions that indicate an existing release, a past release, or a material threat of a release of any hazardous substances or petroleum products into structures on the property or into the ground, groundwater, or surface water of the property. The Phase I ESA found no reported incidents of spills or other contaminant releases at that site. No listed hazardous waste sites were located within various radii (e.g., National Priority List [Superfund] sites within one-half mile; Resource Conservation and Recovery Act [RCRA] hazardous waste treatment, storage, or disposal faculties within one-half mile, and RCRA Corrective Action sites within one mile). No evidence of past or current contamination at the site was visible in aerial photographs, or described in interviews with site

1 The tanks are a nominal 14,000-gallon capacity but actually have 13,000 gallons usable capacity, as they have unusable space due to overflow fittings.

2 Permitted hazardous materials uses are facilities that use hazardous materials or handle hazardous wastes but comply with current hazardous materials and hazardous waste regulations.

3 Environmental cases are sites suspected of releasing hazardous substances or that have had cause for hazardous materials investigations and are identified on regulatory agency lists. These are sites where soil and/or groundwater contamination is known or suspected to have occurred.

4 Spill sites are locations where a spill has been reported to the state or federal regulatory agencies. Such spills do not always involve a release of hazardous materials.

personnel. During a May 31, 2007 reconnaissance at the Tesla Portal site, AGS found that hazardous materials were properly managed.

AGS found three de minimis environmental conditions at the Tesla Portal site. Under ASTM E1527-05, de minimis conditions generally do not present a threat to human health or the environment and generally would not be the subject of an enforcement action if brought to the attention of appropriate governmental agencies. Conditions determined to be de minimis are not recognized environmental conditions, and would not create a significant impact under the CEQA significance criteria set out in Section 4.14.3. The three conditions were:

- The sewage at the site goes into a septic system with an underground storage tank (UST) and a leach field, which is located west of the facility caretaker's house. During the site reconnaissance, the ground surface in the area of the septic system was wet, possibly indicating a leak.

- During the site reconnaissance, there were two ASTs in the northwest area of the site, at a fenced area not under SFPUC control where there were vehicles and farm equipment. One AST was on the ground and was empty. This AST was marked "Elissagara Sheep-Cattle." The other AST was on wheels and it could not be determined whether or not there was anything inside of it. This AST was marked "3E Ranch." Neither AST belongs to the SFPUC.

- There is a dump site in a ravine, outside of SFPUC property, located along the west side of the dirt road that goes up to the three potable water storage ASTs, which is just beyond western boundary of the property and not under SFPUC control. Miscellaneous debris has been dumped into this ravine and burned. During the site reconnaissance, the refuse items in this ravine included large household appliances, tires and car parts, animal bones, 55-gallon drums, and other buckets and containers. The drums and containers checked were empty at the time of the site reconnaissance, but some items may have been concealed underneath other debris. The terminus of this ravine is near the west to northwest boundary of the property.

Thomas Shaft Site

The Thomas Shaft site has three 8,000-gallon (of which 6,000 gallons is usable) hypochlorite tanks and one 2,025-gallon waste storage AST. No hazardous wastes are generated at the site (CCSF 1998). Due to the small scale of current and historic operations at the Thomas Shaft site, its remote location, and the limited scope of improvements and excavation that would be involved under the proposed project, a Phase I ESA was not performed at this site.

4.13.2 Regulatory Framework

Hazardous materials, defined in Section 25501(h) of the California Health and Safety Code, are materials that, because of their quantity, concentration, or physical or chemical characteristics, pose a substantial present or potential hazard to human health and safety or to the environment if

released to the workplace or environment. Hazardous materials have been and are commonly used in commercial, agricultural, and industrial applications as well as in residential areas to a limited extent. A waste is any material that is relinquished, recycled, or inherently waste-like. In accordance with Title 22 of the California Code of Regulations, Division 4.5, Chapter 11, a waste is considered a hazardous waste if it is toxic (causes adverse human health effects), ignitable (has the ability to burn), corrosive (causes severe burns or damage to materials), or reactive (causes explosions or generates toxic gases) in accordance with the criteria established in Article 3. Article 4 lists specific hazardous wastes and Article 5 identifies specific waste categories, including RCRA hazardous wastes, non-RCRA hazardous wastes, extremely hazardous wastes, and special wastes.

Hazardous materials and hazardous wastes are subject to numerous federal, state, and local laws and regulations intended to protect health and safety and the environment. The major federal, state, and regional agencies enforcing these regulations include the U.S. Environmental Protection Agency (U.S. EPA, federal); the Department of Toxic Substances Control (DTSC) and the Regional Water Quality Control Boards (RWQCBs) of the California Environmental Protection Agency (Cal-EPA, state); and the San Joaquin Valley Unified Air Pollution Control District (regional). The state and federal regulatory framework is described below.

Federal Regulations – General Hazardous Materials

The U.S. EPA is the lead agency responsible for enforcing federal regulations that affect public health or the environment. The primary federal laws and regulations include: the Resource Conservation and Recovery Act of 1974 (RCRA); the Comprehensive Environmental Response, Compensation and Liability Act of 1980 (CERCLA); and the Superfund Amendments and Reauthorization Act of 1986 (SARA). Federal statutes pertaining to hazardous materials and wastes are contained in Title 40 of the Code of Federal Regulations.

RCRA was enacted to provide a general framework for the national hazardous waste management system, including the determination of whether hazardous wastes are being generated, techniques for tracking wastes to eventual disposal, and the design and permitting of hazardous waste management facilities. In 1984, the Hazardous and Solid Waste Amendment was enacted to better address hazardous waste; this amendment began the process of eliminating land disposal as the principal hazardous waste disposal method. Other specific areas covered by the amendment include the regulation of carcinogens, listing and delisting of hazardous wastes, permitting for hazardous waste facilities, and leaking underground storage tanks. CERCLA, also known as Superfund, was enacted to ensure that a source of funds was available to clean up abandoned hazardous waste sites, compensate victims, address releases of hazardous materials, and establish liability standards for responsible parties. SARA amended CERCLA in 1986 to increase the Superfund budget, modify contaminated site clean up criteria and schedules, and revise settlement procedures. SARA also provides a regulatory program and fund for underground storage tank cleanups and the Emergency Planning and Community Right-to-Know Program.

In 1976, Congress passed the Toxic Substances Control Act (TSCA) which was implemented in 1979. This act governs the manufacture, processing, distribution in commerce, use, cleanup, storage, and disposal of polychlorinated biphenyls (PCBs). Since 1978, the U.S. EPA has promulgated numerous rules further addressing all aspects of the life cycle of PCBs. The most recent rule was the "Final Rule: Amendments to the TSCA PCB Disposal Regulations Including Amendments to the PCB Notification and Manifesting Rule" promulgated on June 24, 1999. This rule is deregulatory in nature and provides individuals with more flexibility in their PCB disposal practices while continuing to provide protection from unreasonable risk.

State and Regional Regulations – General Hazardous Materials

The California DTSC and the RWQCB are the primary state agencies regulating hazardous materials in California. These agencies are part of the Cal-EPA. The RWQCB is authorized by the State Water Resources Control Board to enforce provisions of the Porter-Cologne Water Quality Control Act of 1969. This act gives the RWQCB authority to require groundwater investigations when the quality of groundwater or surface waters of the state is threatened, and to require remediation of the site if necessary. The DTSC is authorized by the U.S. EPA to regulate the management of hazardous substances, including the remediation of sites contaminated by hazardous substances. California hazardous materials laws incorporate federal standards but are often stricter than federal laws. The primary state laws include: the California Hazardous Waste Control Law (HWCL), the state equivalent of RCRA; and the Carpenter-Presley-Tanner Hazardous Substances Account Act (HSAA), the state equivalent of CERCLA. State hazardous materials and waste laws are contained in the California Code of Regulations, Titles 22 and 26.

The HWCL, enacted in 1972 and administered by the DTSC, is the basic hazardous waste statute in California and has been amended several times to address current needs, including bringing the state law and regulations into conformance with federal laws. This act implements the RCRA "cradle-to-grave" waste management system in California but is more stringent in its regulation of non-RCRA wastes, spent lubricating oil, small-quantity generators, transportation and permitting requirements, as well as in its penalties for violations. The HWCL also exceeds federal requirements by mandating the recycling of certain wastes, requiring certain generators to document a hazardous waste source reduction plan, requiring permitting for federally exempt treatment of hazardous wastes by generators, and implementing stricter regulation of hazardous waste facilities.

The HSAA, enacted in 1981, addresses similar concerns as CERCLA. The primary difference is in how liability is assigned for a site with more than one responsible party. This is important for petroleum cleanup sites because federal law is usually used to force responsible-party cleanups; state law is used for petroleum cleanup sites that are exempt from CERCLA.

Other relevant State of California statutes include:

- The Toxic Pit Cleanup Act of 1984 and the Toxic Injection Well Act of 1985, which were established to provide a regulatory framework for open pits or injection wells as a means of hazardous waste or disposal.

- The Hazardous Waste Management Act of 1986, which coordinates the state's implementation of federal landfill bans and authorizes landfill bans for non-RCRA hazardous wastes.

- The Aboveground Petroleum Storage Act of 1989, which requires the owner or operator of aboveground petroleum storage tanks to file a storage statement with the State Water Resources Control Board if tank storage exceeds 10,000 gallons and holds petroleum or petroleum product that is liquid at ambient temperatures. In addition, the tank or tanks must be registered if they are subject to federal requirements; this potentially expands the requirement for a storage statement to any tank over 660 gallons or aggregate storage of 1,320 gallons.

- The Hazardous Waste Source Reduction and Management Act which, beginning in 1991, required large-quantity generators to document the hazardous wastes being generated and to prepare a documented waste reduction plan.

- The Hazardous Waste Treatment Permitting Reform Act of 1992, which required a permit for any hazardous waste treatment by a generator beginning on April 1, 1993. This statute established a new, tiered permitting program whereby onsite treatment facilities are permitted or authorized to operate subject to different levels of regulatory requirements, depending on the nature and size of the treatment activity. Amendments to this statute adopted in 1993–1996 have enacted certain exemptions and modified compliance requirements.

- The Hazardous Waste Management Reform Act of 1995, which required the DTSC to revise its regulations to more closely conform to federal hazardous waste identification criteria and essentially eliminate land disposal restrictions for California-only hazardous wastes, among other major changes. However, many of these changes have been deferred to a DTSC advisory committee for further study and are not expected to be implemented for several years, and in certain cases, not at all.

Use and Storage of Hazardous Materials and Fuels

In accordance with Chapter 6.11 of the California Health and Safety Code (Section 25404 et seq.), local regulatory agencies enforce many federal and state regulatory programs through the CUPA program, including:[5]

[5] Local regulatory agencies also regulate USTs under Chapter 6.7 of the California Health and Safety Code, Section 25280 et seq. However, no USTs would be installed under the proposed project.

- Hazardous materials business plans (Chapter 6.95 of the Health and Safety Code, Section 25501 et seq.)
- The California accidental release prevention program for acutely hazardous materials (Chapter 6.95 of the Health and Safety Code, Section 25531 et seq.)
- State Uniform Fire Code requirements (Section 80.103 of the Uniform Fire Code as adopted by the state fire marshal pursuant to Health and Safety Code, Section 13143.9)
- Aboveground storage tanks (Health and Safety Code Section 25270.5[c])
- Hazardous waste generator requirements (Chapter 6.5 of the Health and Safety Code, Section 25100 et seq.)

Hazardous Materials Business Plans

Businesses that handle specified quantities of chemicals are required to submit a Hazardous Materials Business Plan (HMBP) in accordance with community right-to-know laws. This plan allows local agencies to plan appropriately for a chemical release, fire, or other incident. The HMBP must include the following:

- An inventory of hazardous materials with specific quantity data, storage or containment descriptions, ingredients of mixtures, and physical and health hazard information
- Site and facility layouts that must be coded for chemical storage areas and other facility safety information
- Emergency response procedures for a release or threatened release of hazardous materials
- Procedures for immediate notification of releases to the administering agency
- Evacuation plans and procedures for the facility
- Descriptions of employee training in evacuation and safety procedures in the event of a release or threatened release of hazardous materials consistent with employee responsibilities, and proof of implementing such training on an annual basis
- Identification of local emergency medical assistance appropriate for potential hazardous materials incidents

The HMBP is filed with and administered by the CUPA agency, which ensures review by and distribution to other potentially affected agencies. The SFPUC has prepared and implemented HMBPs for its facilities, including Tesla Portal and Thomas Shaft, that use hazardous materials above threshold limits.

HMBPs specify response procedures to be implemented in the event of a chemical emergency, in accordance with the applicable local regulations. These procedures include notification requirements in the event of a spill; measures to be taken to control and cleanup a spill;

procedures for coordination of emergency response personnel; and procedures to be followed should emergency evacuation be required. Plant personnel maintain a comprehensive inventory of emergency response equipment at the facilities concerned, and emergency response equipment is regularly inspected and maintained. In accordance with community right-to-know laws, a copy of the HMBP is on file with local fire departments to assist them in responding to chemical emergencies. These emergency response procedures would apply to the proposed project.

Aboveground Storage of Petroleum Products

The Aboveground Petroleum Storage Act of 1990 requires facilities storing petroleum products in a single tank greater than 1,320 gallons or facilities storing petroleum in aboveground tanks or containers with a cumulative storage capacity of greater than 1,320 gallons to file a storage statement with the State Water Resources Control Board (SWRCB) and prepare a spill prevention, control, and countermeasure plan. The plan must identify appropriate spill containment or equipment for diverting spills from sensitive areas, and discuss facility-specific requirements for the storage system, inspections, record keeping, security, and personnel training.

The SWRCB requires registration of an aboveground fuel storage tank at a construction site only if the tank is 20,000 gallons or larger, or if the aggregate volume of aboveground petroleum storage is over 100,000 gallons. These large tanks would not be present at the project sites. For smaller temporary tanks used during construction, methods for controlling a release and measures to clean up an accidental release and prevent degradation of water quality are addressed in the construction stormwater pollution prevention plan prepared for the project, as described in Section 4.5, Hydrology and Water Quality.

Hazardous Materials Worker Safety Requirements

The federal Occupational Safety and Health Administration (Fed-OSHA) and the California Occupational Safety and Health Administration (Cal-OSHA) are the agencies responsible for assuring worker safety in the handling and use of chemicals in the workplace. The federal regulations pertaining to worker safety are contained in Title 29 of the Code of Federal Regulations, as authorized in the Occupational Safety and Health Act of 1970. They provide standards for safe workplaces and work practices, including standards relating to hazardous materials handling. In California, Cal-OSHA assumes primary responsibility for developing and enforcing workplace safety regulations; Cal-OSHA standards are generally more stringent than federal regulations.

The state regulations concerning the use of hazardous materials in the workplace are included in Title 8 of the California Code of Regulations, which contain requirements for safety training, availability of safety equipment, accident and illness prevention programs, hazardous substance exposure warnings, and emergency action and fire prevention plan preparation. Cal-OSHA also enforces hazard communication program regulations, which contain worker safety training and hazard information requirements, such as procedures for identifying and labeling hazardous

substances, communicating hazard information relating to hazardous substances and their handling, and preparation of health and safety plans to protect workers and employees.

The California Public Resources Code, beginning with Section 4427, includes fire safety regulations that: restrict the use of equipment that may produce a spark, flame, or fire; require the use of spark arrestors[6] on construction equipment that use an internal combustion engine; specify requirements for the safe use of gasoline-powered tools in fire hazard areas; and specify fire suppression equipment that must be provided onsite for various types of work in fire prone areas.

4.13.3 Impacts

Significance Criteria

The City and County of San Francisco (CCSF) has not formally adopted significance standards for impacts related to hazards, but generally considers that implementation of a proposed project would have a significant impact if it were to:

- Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials
- Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment
- Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within 1/4 mile of an existing or proposed school
- Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would create a significant hazard to the public or the environment
- For a project located within an area covered by an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, result in a safety hazard for people residing or working in the project area
- For a project within the vicinity of a private airstrip, result in a safety hazard for people residing or working in the project area
- Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan

[6] A spark arrestor is a device that prohibits exhaust gases from an internal combustion engine from passing through the impeller blades where they could cause a spark. A carbon trap is commonly used to retain carbon particles from the exhaust.

- Expose people or structures to a significant risk of loss, injury, or death involving fires

Areas of No Project Impact

Several of the above significance criteria are *not applicable* to the proposed project, as there either is no potential for the impact to occur, or the applicable environmental resource does not occur within the project area. The proposed project sites are not within 1/4 mile of an existing or proposed school, are not listed on the Cortese List, are not located within two miles of a public airport or within an area covered by an airport land use plan, and are not located in the vicinity of a private airstrip. Therefore, the proposed project would have no impact with respect to these significance criteria.

Approach to Analysis

The analysis of hazardous materials evaluates potential short-term and long-term impacts associated with the construction and operation of the proposed project at the Tesla Portal and Thomas Shaft sites in regards to:

- The potential for accidental hazardous materials release from construction equipment
- The potential risk of fires during construction
- The potential for interference with an emergency response plan

Construction Impacts

Impact 4.13-1: Potential to encounter hazardous materials in soil and groundwater (Tesla Portal: LS; Thomas Shaft: LS)

Existing water treatment operations and site maintenance at the Tesla Portal and Thomas Shaft sites involve the use of chemicals. Also, since the sites are located in areas of past agricultural use, it is possible that historical uses of pesticide, herbicides, or other hazardous materials occurred at the sites. If hazardous materials were released to soil or groundwater, workers and persons outside the facility fencelines could be exposed to such materials during excavation and other construction operations, and a further release to the environment could occur. Depending on the nature and extent of any contamination encountered, adverse health and environmental effects could result if proper precautions are not taken. If encountered, contaminated soil and groundwater could also require disposal as hazardous waste.

Tesla Portal Site

Although no known contamination exists in the vicinity of where construction would occur, the possibility remains that unrecorded hazardous materials contamination from past operations may have occurred at the Tesla Portal site. If contaminated soil or groundwater were encountered at this site, implementation of standard SFPUC construction measures, which are part of the project,

would address previously unidentified hazardous substances. SFPUC Construction Measure #7 for hazardous materials requires that a site assessment be conducted by a qualified environmental professional no more than three months before construction, and that a contingency plan be prepared identifying measures to be taken should unanticipated contamination be identified during construction. If actual or suspected hazardous substances (e.g., soils with fuel or chemical odors) were discovered, activities would proceed in accordance with the contingency plan (e.g., sampling would be necessary to identify the substances present, and the appropriate regulatory agencies would be notified).

Based on the existing conditions at the Tesla Portal site as documented in the Phase I ESA (AGS, 2007), the likelihood that contaminated soil or groundwater would be encountered during construction of the proposed project at that site is low; therefore, the impact would be considered less than significant.

Thomas Shaft Site

Due to the small scale of current and historic operations at the Thomas Shaft site, its remote location, and the limited scope of proposed improvements and excavation, a Phase I ESA was not performed at this site. The likelihood that contaminated soil or groundwater would be encountered during construction at the Thomas Shaft site is low; therefore, the impact would be considered less than significant.

Impact 4.13-2: Accidental hazardous materials release from construction equipment (Tesla Portal: LS; Thomas Shaft: LS)

Construction operations would include the use of hazardous materials such as motor fuels, oil, solvents, and lubricants. An accidental release of hazardous materials could occur from storage of such hazardous materials at the Tesla Portal and Thomas Shaft sites. Apart from contaminating soil, releases could reach the wetland area at the Tesla Portal site, and degrade water quality.

The potential that an accidental release would occur would be reduced by the use of standard operating procedures for the safe storage and use of hazardous materials. All users of hazardous materials would be required to comply with state and federal occupational safety and health codes and regulations, and any unused hazardous material would be removed from the site when work is complete. Nonhazardous waste would be disposed of at an approved landfill.

In addition, the project would comply with SFPUC Construction Measure #3 for water quality, which requires the implementation of erosion control measures, including preparation and implementation of a Storm Water Pollution Prevention Plan (SWPPP) as required by the RWQCB. The SWPPP is required for all projects disturbing more than one acre of land and therefore would be required for the Tesla Portal site. The SWPPP would include protection measures for the temporary onsite storage of diesel fuels used during construction, including

requirements for secondary containment and berming of the diesel storage area or any chemical storage areas to contain a potential release and to prevent any such release from reaching an adjacent waterway or stormwater collection system.

Based on the above factors, impacts from accidental releases would be less than significant.

Impact 4.13-3: Risk of fires during construction (Tesla Portal: LS; Thomas Shaft: LS)

The use of construction equipment could pose a wildland fire risk at the Tesla Portal site and, to a lesser extent, at the Thomas Shaft site, as vegetation (mostly grasses) is present at both sites. The time of the greatest fire danger is during the clearing phase, when people and machines are working among vegetative fuels that can be highly flammable; if piled onsite, the cleared vegetative materials could also become a fire fuel. Potential sources of ignition include equipment with internal combustion engines, gasoline-powered tools, and equipment or tools that produce a spark, fire, or flame. Such sources include sparks from blades or other metal parts scraping against rock, overheated brakes on wheeled equipment, friction from worn or unaligned belts and drive chains, and burned-out bearings or bushings. Sparking as a result of scraping against rock is difficult to prevent. The other hazards result primarily from poor maintenance of the equipment. Smoking by onsite construction personnel is also a potential source of ignition during construction.

Fire protection services, at both the Tesla Portal and Thomas Shaft sites, are provided by the City of Tracy Fire Department. Two fire stations, Station 95 and Station 93, provide fire protection services to both project sites. Station 95 is approximately four miles from Tesla Portal and eight miles from Thomas Shaft. Station 93 is approximately 5.5 miles from Tesla Portal and 10 miles from the Thomas Shaft site (refer to Public Services Section 4.11 for further information regarding fire protection services). Additionally, the new facilities at the Tesla Portal site would include a combination of conventional water sprinklers, dry chemical systems and fire hydrants for onsite fire protection. Water for the building sprinkler systems would be provided by gravity from existing utility water tanks. The site also includes on-site fire hydrants supplied by fire pumps fed directly from the San Joaquin Pipelines that enter the site. The Thomas Shaft site has an existing 5,000-gallon water tank with a pump for onsite fire protection.

Regulations governing the use of construction equipment in fire prone areas are designed to minimize the risk of wildland fires during construction activity. In accordance with the Public Resources Code, the construction contractor would be required to comply with the following requirements during construction activities:

- Earthmoving and portable equipment with internal combustion engines would be equipped with a spark arrestor to reduce the potential for igniting a wildland fire (Public Resources Code [PRC] Section 4442).

- Appropriate fire suppression equipment would be maintained during the highest fire danger period – from April 1 to December 1 (PRC Section 4428).

- On days when a burning permit is required, flammable materials would be removed to a distance of 10 feet from any equipment that could produce a spark, fire, or flame, and the construction contractor would maintain the appropriate fire suppression equipment (PRC Section 4427).

- On days when a burning permit is required, portable tools powered by gasoline-fueled internal combustion engines would not be used within 25 feet of any flammable materials (PRC Section 4431).

Compliance with the Public Resources Code would ensure that impacts related to wildland fires would be less than significant.

Impact 4.13-4: Interference with emergency response plan (Tesla Portal: LS; Thomas Shaft: LS)

Project construction would not require the use of public roadways for construction staging and equipment parking. Additionally, no lane or road closures are anticipated. Thus, it is not likely that project construction activities could impede access for emergency response vehicles, interfere with an emergency response plan or emergency evacuation plan. In addition, SFPUC Construction Measure #5, which includes preparation and implementation of a traffic control plan, would be implemented as part of the project to minimize impacts on traffic flow. Therefore, impacts associated with interference with an emergency response plan would be less than significant.

Operational Impacts

Impact 4.13-5: Increased use of hazardous materials during operation (Tesla Portal: LS; Thomas Shaft: LS)

Existing water treatment operations and site maintenance at the Tesla Portal and Thomas Shaft sites involve the use of chemicals. At both Thomas Shaft and Tesla Portal sites, the primary potential hazardous materials impacts posed by the proposed project are increased risks of spillage of liquid chemicals, particularly the sodium hypochlorite described above. Chemical spillage could occur during normal operations, due to equipment malfunction or operator error, or be caused by natural hazards, such as seismic events. If acids were to mix with sodium hypochlorite (a base chemical), a dangerous chemical reaction could occur (e.g., chlorine gas could be produced). Whether singly or mixed, if accidentally released, these chemicals could

cause health effects to workers, and less likely, to persons outside the facility fencelines. Releases also could cause adverse environmental effects.

These risks would be minimized in several ways:

Regulatory compliance. Both Tesla Portal and Thomas Shaft sites would comply with all applicable hazardous materials regulations, as well as SFPUC standard construction measures. Regulatory requirements also affect the design features discussed below.

Protective design features. The proposed improvements at both the Tesla Portal and Thomas Shaft sites would incorporate design features to reduce the chances that spillage would occur, and reduce the consequences of such spills.

The Uniform Fire Code and the California Fire Code, Article 80 (Hazardous Materials), include specific requirements for the safe storage and handling of hazardous materials. These requirements reduce the potential for a release of hazardous materials and for mixing of incompatible chemicals. Design of chemical storage facilities at the Tesla Portal and Thomas Shaft sites would comply with the current Uniform Fire Code and other applicable federal, state, and local regulations, including the following specific design features that would reduce the potential for a release of hazardous materials that could affect public health or the environment.

Both projects would be subject to:

- A requirement to separate incompatible materials. Acids would be isolated from sodium hypochlorite as required by the Fire Code, kept either in a separate area at least 25 feet away, or separated by a four-hour firewall.

- Spill control in all storage, handling, and dispensing areas.

- Separate secondary containment for each chemical storage system. The secondary containment would hold the entire contents of the tank, plus the volume of water needed to supply the fire suppression system for a period of 20 minutes in the event of a catastrophic spill.

The project includes design provisions for secondary containment for chemical storage tanks and feed pipelines, in accordance with applicable regulations.

Emergency response procedures. The HMBPs for the Tesla Portal and Thomas Shaft sites specify emergency response procedures for spills of liquid materials, releases of compressed gases, and spills of solid or powder materials. As well as procedures for controlling spills (e.g., by applying absorbent material to liquid spill areas) and reducing related hazards (e.g., by removing sources of ignition), the HMBPs include procedures for contacting emergency responders, such as the Tracy Fire Department; notifying regulatory agencies; alerting employees and other people within the facilities of emergencies; and evacuating personnel. No evacuations in response to spills or other emergencies have been necessary at either facility, and no evacuation drills are considered

necessary. No problems that would necessitate alerting people outside the facilities (e.g., in Chrisman) are anticipated.

Emergency response equipment is periodically inspected and tested, and employees are trained in environmental compliance and health and safety compliance. In accordance with community right-to-know laws, a copy of the HMBP is on file with the local fire department to assist them in responding to chemical emergencies at the SFPUC chemical storage facilities.

Transportation hazards. The expansion of operations at both project sites would increase the number and quantities of hazardous materials used. This would increase the number of chemical deliveries over baseline levels and indirectly result in an incremental increase in the potential for accidents during transport. These increases would have less than significant effects. The transport of hazardous materials and wastes is regulated by the California Department of Transportation and the California Highway Patrol. These agencies regulate container types and packaging requirements as well as licensing and training for truck operators, chemical handlers, and hazardous waste haulers. Because the SFPUC and all service providers are and would continue to be required to comply with existing and future hazardous materials laws and regulations for the transport of hazardous materials, the risk of accidental releases of hazardous materials during normal transport operations would be low and would not constitute a significant hazard.

Tesla Portal Site

Regulatory compliance. To meet regulatory guidelines, the SFPUC would be required by the local CUPA agency (San Joaquin County Environmental Health Department) to prepare an updated HMBP for the new facilities at Tesla Portal to reflect the changes in chemical storage. Currently, the Tesla Portal site has two 13,000 gallon and four 4,000 gallon ASTs containing sodium hypochlorite. Other hazardous materials at the Tesla Portal site include a 1,000 gallon propane AST, sodium thiosulfate, and small quantities of chemicals used for maintenance activities. The proposed project would include three 16,000-gallon sodium hypochlorite tanks, two 10,000 gallon fluoride tanks, two 3,000 gallon food grade acid tanks, two 15,000 gallon aboveground diesel fuel tanks, two 12,500 gallon CO_2 tanks, and 12 UV reactors each containing minimal amounts of mercury. The addition of the three 16,000 gallon hypochlorite tanks represents a total increase of 6,000 gallons of sodium hypochlorite stored at the site. The addition of fluoride, diesel fuel, food grade acid, CO_2, and UV reactors would represent new materials that are not currently present or used at the site.

The installation of a UV disinfection system (12 UV reactors) at the Tesla Portal site would introduce a new potential hazard, as the UV lamps that would be used in the project contain small amounts of mercury.[7] There have been few lamp breakages at existing UV facilities, and in the judgment of the U.S. EPA, the risk to human health and the environment from the mercury in UV lamps used in the treatment of drinking water is very small. Risks can be addressed through

[7] The mercury content in a single UV lamp typically ranges from 0.005 – 0.4 grams. In comparison, the mercury content of a typical oral/rectal/baby thermometer that uses mercury is 0.61 grams (U.S. EPA, 2002).

engineering and administrative methods to prevent UV lamp breaks, and exposure to mercury if breaks do occur (U.S. EPA, 2006). Appendix E of the U.S. EPA, *Ultraviolet Disinfection Guidance Manual For The Long Term 2 Enhanced Surface Water Treatment Rule,* November 2006, provides direction on how to prevent breakage of UV lamps during transport and operation and guidance on how operators may limit exposure to mercury if a break should occur while the water treatment system is on or offline. Some of these methods include, but are not limited to:

- Installation of spring actuated valves with a short closure time on the reactor inlet and outlet piping in order to isolate the mercury in the reactor downstream

- Installation of a strainer on the reactor outlet piping to collect condensed mercury and quartz fragments should a break occur

- The preparation and implementation of an On-line Lamp Break Response Plan

In addition to compliance with the engineering and administrative measures prescribed in Appendix E of the *Ultraviolet Disinfection Guidance Manual For The Long Term 2 Enhanced Surface Water Treatment Rule,* November 2006, the SFPUC has included its own protection measures in the Draft Design Criteria for the proposed Tesla Portal Treatment Facility (SFPUC 2006). These measures would further limit potential hazards associated with UV lamp breakage. The Design Criteria state that, "the UV system shall be designed to prevent dissolved mercury from entering the Hetch Hetchy Aqueduct system in the case of lamp breakage. Mercury minimization shall include the following measures:

- Provision of a slow velocity / in-line baffle / quiescent zone downstream of the UV reactors on the main outlet pipe manifold for each UV train to help mitigate the risk from a potential mercury release and settle out glass fragments and solid-state mercury. The zone shall have a blowoff for removal of settled materials.

- The UV lamps shall not be installed until a designated volume of water has passed through the UV reactors at startup. This limits the risk of breaking lamps due to construction debris left in the system.

- Emergency Response Plans shall be developed to address potential hazardous material contamination of the water supply. These plans shall consider the appropriate response to be implemented in the unlikely event of a mercury release to the water supply."

Due to their mercury content, spent UV lamps are considered hazardous waste under RCRA. Expended lamps would be sent to a mercury recycling facility where the mercury is recovered and lamp components are recycled.

Protective design features. At the Tesla Portal site, the loading area would be designed either to have its own secondary containment or to drain to the tank containment area. These measures would provide containment in the event that a chemical spill occurred during transfer or storage.

Chemical loading would occur within a covered area to prevent rain from draining into the containment sump. Any chemical spillage into the secondary containment areas would be pumped and disposed of, depending on the chemical, in accordance with any applicable regulations.

Sodium hypochlorite deteriorates with exposure to heat. At the new Chemical Process Building, passive cooling would be used to keep storage areas cool. The chemical storage tank area would have an exhaust ventilation rate corresponding to Hazardous (H) Occupancy of the California Building Code.

At the Tesla Portal site, fire protection would be provided for the new facilities by a combination of conventional water sprinklers, dry chemical systems and fire hydrants. Water for the sprinklers would be provided by gravity from existing utility water tanks. The fire hydrants would be supplied by fire pumps fed directly from the San Joaquin Pipelines that enter the site.

Transportation hazard. At the Tesla Portal site, deliveries of sodium hypochlorite would remain about the same as current levels, about one delivery every one to five days. Approximately one to three deliveries per week apiece of fluoride, sulfuric acid, and food-grade acid would occur.

Though the proposed project would provide a marginal increase in the amount of hazardous materials stored at the Tesla Portal Site, implementation of regulatory requirements, project design features, and protective measures described above would reduce potential impacts to a less-than-significant level.

Thomas Shaft Site

Regulatory compliance. The Thomas Shaft site currently has three 6,000-gallon sodium hypochlorite tanks which would remain unchanged with implementation of the proposed project. The project would, however, add two UV reactors which contain minimal amounts of mercury. Thus, the HMBP for the existing Thomas Shaft facility would require updating.

To comply with Fire Code, fire extinguishers would continue to be available for use. The site also has an existing 5,000-gallon water tank with a pump for fire protection.

Transportation hazard. The Thomas Shaft site would continue to receive deliveries of food grade acid once a month including acid needed to clean the UV system. Therefore, the number of monthly delivery trips would remain unchanged.

4.14 Energy Resources

4.14.1 Setting

California's Electricity Supply

California's electricity is supplied by a number of sources, including natural gas (41 percent), coal (21 percent), large hydroelectric plants (15 percent), and nuclear (13 percent) (CEC, 2005). The remaining 10 percent is supplied from geothermal, biomass, small hydroelectric, wind, and solar sources. Despite California policies aimed at diversifying the state's electrical supply, dependence on natural gas is continuing to grow, from 30 percent in 1999 to 36 percent in 2002 to 41 percent in 2004. Electricity generation accounted for 50 percent of the natural gas usage in 2004. In 2002, California imposed a requirement that electrical corporations increase procurement of eligible renewable energy resources by at least 1 percent per year so that 20 percent of its retail sales are procured from renewable resources by 2017 (Public Utilities Code, Section 399.15), and publicly owned utilities have been asked to consider establishing a similar target.

Electrical Utility Providers

SFPUC Power Enterprise

San Francisco Public Utilities Commission (SFPUC) Power Enterprise (formerly part of Hetch Hetchy Water and Power Enterprise) provides electricity, primarily from power generated by the SFPUC's hydroelectric facilities in the Hetch Hetchy system, to all City and County of San Francisco (CCSF) facilities (including tenants), including the Tesla Portal and Thomas Shaft sites. The Hetch Hetchy system comprises 400 megawatts of hydroelectric power generation plants on the Tuolumne River and 150 miles of high-voltage transmission lines linking Hetch Hetchy power to California's electricity grid at Newark.

Energy production varies by season and by year depending on hydrologic conditions. The long-term annual average production is approximately 1.7 billion kilowatt-hours (kWh); historical production has ranged from a low of 1.2 billion kWh per year to a high of 2.2 billion kWh per year (SFPUC, 2002).

Pacific Gas and Electric Company

Pacific Gas and Electric Company (PG&E) provides natural gas and electricity to most of Northern California. It provides SFPUC Power Enterprise with transmission and distribution services from Newark to the west, pursuant to an Interconnection Agreement regulated by the Federal Energy Regulatory Commission. Under this agreement, PG&E also transmits and distributes electricity to SFPUC Power Enterprise customers, including the Tesla Portal and Thomas Shaft sites.

Current Energy Use

While per capita electricity consumption in the United States has increased by nearly 50 percent over the past 30 years, per capita California energy use during this period has been approximately flat (CEC, 2005). This achievement is the result of continued progress in cost-effective building and appliance standards and ongoing enhancements in efficiency programs. These combined efforts have reduced peak capacity needs by more than 12,000 megawatts and continue to save about 40,000 gigawatt-hours (GWh) per year of electricity.

Electricity consumption in California grew from 250,241 GWh in 2001 to 270,927 GWh in 2004. Electricity use is forecast to grow between 1.2 and 1.5 percent annually, from 270,927 GWh in 2004 to between 310,716 and 323,372 GWh by the end of 2016. Overall, electricity demand in California increases most dramatically in the summer, driven by high air-conditioning usage. The electricity generation system must accommodate high summer peaks in addition to demand swings caused by weather variability and the economy. Although peak demand periods total only 50 to 100 hours per year, they impose huge burdens on the electrical system. The state's dependence on natural gas to generate electricity is escalating, as is the demand for natural gas in the residential and commercial sectors, with California's natural gas consumption second only to that of Texas.

Despite improvements in power plant licensing, energy efficiency programs, and continued technological advances, development of new energy supplies is not keeping pace with the state's increasing demand (CEC, 2005). Construction of new power plants has lagged, and the number of new plant permit applications has decreased. Transmission lines are frequently running at capacity, forcing system operators to reduce generation to avoid overloading the system, and transmission line outages sometimes result in rolling blackouts. In addition, the development of new renewable resources has been slower than anticipated, due in part to the state's approval process. Additional actions are still needed for California to achieve its energy efficiency potential.

In September 2004, the California Public Utilities Commission (CPUC) adopted aggressive energy savings goals for both electricity and natural gas. In achieving these targets, the state will save an additional 5,000 megawatts and 23,000 GWh per year of electricity and 450 million therms per year of natural gas by 2013.

The Hetch Hetchy system provides 400 megawatts of hydroelectric power. SFPUC Power Enterprise customer base and generation base are distinguishable from other power supplies, and its load profile is relatively flat (i.e., not dramatically higher in the summer) because it is not driven by air-conditioning usage. Despite the overall surplus of energy produced, CCSF typically supplements its power supply with PG&E produced power during fall and summer months in order to allow water to be stored while continuing to meet its municipal demand and contractual obligations for power supply.

- Existing energy usage by the SFPUC's regional water system, including energy use at the Tesla Portal and Thomas Shaft sites, is nearly 44 million kWh per year. This is less than four percent of the energy produced by the Hetch Hetchy system (historical low energy production rate), and less than three percent of the long-term annual average production rate (SFPUC, 2008c). Within the SFPUC San Joaquin Region, which encompasses all SFPUC facilities from the western boundary of Tuolumne County through Stanislaus and San Joaquin counties, almost to the east boundary of Alameda County, existing power usage is approximately 200,000 kWh, a fraction of the regional water system's total energy use (SFPUC, 2002).

Tesla Portal

The Tesla Portal site currently uses approximately 175,000 kWh per year for operation of existing facilities.

Thomas Shaft

Operation of existing facilities at the Thomas Shaft site has an average annual energy usage of 70,800 kWh.

4.14.2 Regulatory Framework

2005 California Energy Action Plan II

The *Energy Action Plan II* is the state's principal energy planning and policy document (CPUC and CEC, 2005). The plan continues the goals of the original *Energy Action Plan*, describes a coordinated implementation plan for state energy policies, and identifies specific action areas to ensure that California's energy is adequate, affordable, technologically advanced, and environmentally sound. In accordance with this plan, the first-priority actions to address California's increasing energy demands are energy efficiency and demand response (i.e., reduction of customer energy usage during peak periods in order to address system reliability and support the best use of energy infrastructure). Additional priorities include the use of renewable sources of power and distributed generation (i.e., the use of relatively small power plants near or at centers of high demand). To the extent that these actions are unable to satisfy the increasing energy and capacity needs, clean and efficient fossil-fired generation is supported. The *Energy Action Plan II* includes the following energy efficiency action specific to water supply systems:

- Identify opportunities and support programs to reduce electricity demand related to the water supply system during peak hours, and opportunities to reduce the energy needed to operate water conveyance and treatment systems. In 2002, California established its Renewable Portfolio Standard program,[1] with the goal of increasing the percentage of renewable energy

[1] The Renewable Portfolio Standard is a flexible, market-driven policy to ensure that the public benefits of wind, solar, biomass, and geothermal energy continue to be realized as electricity markets become more competitive. The policy ensures that a minimum amount of renewable energy is included in the portfolio of electricity resources serving a state or country. By increasing the required minimum amount over time, the Renewable Portfolio Standard puts the electricity industry on a path toward increasing sustainability.

in the state's electricity mix to 20 percent by 2017. The CPUC subsequently accelerated that goal to 2010 for electrical corporations, and the CEC further recommended that the state increase the target for all retail electricity sellers to 33 percent by 2020. Because much of electricity demand growth is expected to be met by increases in natural-gas-fired generation, reducing consumption of electricity and diversifying electricity generation resources are significant elements of plans to reduce natural gas demand.

Building Energy Efficiency Standards

The Energy Efficiency Standards for Residential and Nonresidential Buildings, as specified in Title 24, Part 6, of the California Code of Regulations (CCR), were established in 1978 in response to a legislative mandate to reduce California's energy consumption. The standards are updated periodically to allow consideration and possible incorporation of new energy efficiency technologies and methods. The current version of the standards was adopted in October 2005, and the CEC has begun development of an update, which is planned for adoption in 2008.

California's building efficiency standards (along with those for energy-efficient appliances) have saved more than $56 billion in electricity and natural gas costs since 1978 (CEC, 2007). It is estimated that the standards will save an additional $23 billion by 2013.

San Francisco Plans

Section 4.2 describes CCSF plans and policies related to energy resources, including the Sustainability Plan for San Francisco.

4.14.3 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to energy resources, but generally considers that implementation of a proposed project would have a significant energy resource impact if it were to:

- Encourage activities that result in the use of large amounts of fuel, water, or energy, or use these in a wasteful manner

Approach to Analysis

This analysis evaluates the proposed project in terms of energy demand during construction and operation, and assesses the potential for long-term increases in energy demand and/or the wasteful use of energy. For energy used during construction, the analysis discusses how construction operations would be conducted to minimize the use of fuels and ensure that they are not used in a wasteful manner. For energy used during operation, the analysis evaluates energy

efficiency measures associated with project operations, consistent with the California *Energy Action Plan II.* Although any increase in energy demand would be considered potentially significant, implementation of measures to increase energy efficiency would ensure that energy is not used in a wasteful manner and would reduce potential impacts on the state's limited energy supply and aging energy infrastructure.

Construction Impacts

Impact 4.14-1: Construction-related energy use (Tesla Portal: LS; Thomas Shaft: LS)

Project construction would extend over an approximately 24-month period at the Tesla Portal site and an approximately six-month period at the Thomas Shaft site. Construction of the proposed project would require the use of fuels (primarily gas, diesel, and motor oil) for a variety of construction activities, including excavation, grading, and vehicle travel. During these activities, fuel use for construction worker trips to the project sites would be minor compared to the fuel consumption by construction equipment (refer to Table 4.8-1, Tesla Portal Construction Related Trips, and Table 4.8-2, Thomas Shaft Construction Related Trips in Section 4.8, Traffic, Transportation, and Circulation). The wasteful use of fuels during construction would not be economically sustainable for the SFPUC or its contractors. Additionally, as part of the proposed project, actions would be implemented that would reduce greenhouse gas emissions (see Section 3.4.2 of the Project Description); these actions include requiring all contractors to maintain tire inflation to the manufacturers' specifications, which would help to improve fuel efficiency. Certain exhaust control measures specified under Mitigation Measure 4.9-1b (San Joaquin Valley Air Pollution Control District Exhaust Controls), such as limiting idling time and performing monthly maintenance on construction vehicles, would also ensure that fuels are not used in a wasteful manner. Given the scope of the project and associated construction-related vehicle trips, the impact of energy consumption due to fuel use would be less than significant even without implementation of Mitigation Measure 4.9-1b. Therefore, this impact would be less than significant.

Operational Impacts

Impact 4.14-2: Long-term energy use during operation (Tesla Portal: PSM; Thomas Shaft: PSM)

Operation of the proposed project would increase the long-term consumption of energy at both project sites. The SFPUC Power Enterprise currently provides electrical power service to the project sites and would continue as the service provider with project implementation. Although the Hetch Hetchy system produces far greater power than is currently used at the Tesla Portal and Thomas Shaft sites, and that would be used in the operation of the new proposed facilities, the increase in power use associated with the project could result in a higher reliance on nonrenewable energy resources. This is because less hydroelectric power would be available,

particularly during the fall and summer months when power generation under the Hetch Hetchy system is reduced and power supplies are supplemented by PG&E.

Tesla Portal Site

- SFPUC Power Enterprise provides power to the SFPUC's regional water system facilities, which use an estimated total energy usage of approximately 44 million kWh per year. This annual estimate includes the Tesla Portal facilities, which has a current demand of approximately 175,000 kWh per year. Operation of the new facilities at the Tesla Portal site could substantially increase overall on-site energy consumption. The SFPUC estimates that, in total, operation of the proposed improvements at the Tesla Portal site would require approximately six million kWh per year. This estimate includes approximately 1,800,000 kWh for operation of the three new buildings (UV building, Chemical Process building and Office/Control building), approximately 3,550,000 kWh for the UV reactors, and approximately 650,000 kWh for the proposed pumps). Accounting for current energy use at the Tesla Portal site, the project would result in a net increase of approximately 5,825,000 kWh, which represents roughly 13 percent of the regional water system's current annual energy use. As described in the setting, the energy use by the regional water system is a fraction (less than 3 percent) of the long-term annual average energy production of the Hetch Hetchy system, and would remain at approximately three percent including the project's increased operational energy use.

To accommodate the additional demand generated by the proposed improvements, SFPUC would install a ground-mounted transformer adjacent to the UV Building, and an above-ground power line would extend from the existing power pole to the new transformer. Underground lines from the transformer to the Chemical Office/Control Building would also be installed.

The proposed project would be required to meet energy efficiency standards contained in Title 24 of the CCR. SFPUC has also drafted energy efficiency measures that are included in the Draft Design Criteria manual for the Tesla Treatment Facility. The Draft Design Criteria manual provides guidelines for energy and resource use at the Tesla Treatment Facility, which would ensure that energy would not be used in a wasteful manner. The Design Criteria would require improvements at the Tesla Portal site to meet and/or exceed Title 24 energy efficiency standards by a minimum of 5 percent.[2] SFPUC would also consider methods for reducing the carbon footprint[3] of the proposed project by requiring review of the final design by the Power Enterprise Energy Efficiency Group. This review would ensure that any features that would improve energy sustainability are incorporated, as feasible, into the design. SFPUC would also incorporate the use of energy efficient lighting, heating, ventilation, and air conditioning (HAVC) systems.

[2] This minimum 5 percent reduction in energy use includes lighting systems, which would also meet the recommendations of the Illuminating Engineering Society Handbook.

[3] Carbon footprint is a measure of the impact human activities have on the environment in terms of the amount of greenhouse gases produced, measured in units of carbon dioxide. www.carbonfootprint.com

- The project's energy impacts would be reduced to less than significant with implementation of the project design features, described above, and implementation of Mitigation Measure 4.14-1, which would ensure that energy efficient equipment is used in the proposed project at the Tesla Portal site. It would also require the preparation of a repair and maintenance plan for each facility to minimize power use and the use of renewable energy, such as solar power, at the Tesla Treatment Facility.

The two standby power generators that would be installed at the Tesla Portal site would be fueled by diesel, a nonrenewable energy source. However, standby power would only be used in the event of a disruption in power service and, therefore, impacts related to the use of large amounts of energy would be less than significant for these generators.

Thomas Shaft Site

Current average annual consumption at the Thomas Shaft site is 70,800 kWh per year and would increase to 110,800 kWh annually with implementation of the project. This increase in energy use would represent a potentially significant increase in energy use. However, implementation of Mitigation Measure 4.14-1, which requires energy efficiency measures consistent with the California *Energy Action Plan II*, would reduce this impact to a less-than-significant level.

4.15 Cumulative Effects

4.15.1 Introduction

As defined in the California Environmental Quality Act (CEQA) Guidelines Section 15355, a cumulative impact refers to two or more individual effects that, when considered together, are considerable or that compound or increase other environmental impacts. CEQA Guidelines Section 15130(a) requires that an environmental impact report (EIR) include a discussion of cumulative impacts "…when the project's incremental effect is cumulatively considerable." According to the Guidelines, cumulatively considerable means a project's incremental effects are significant when viewed in connection with the effects of past, present, and reasonably foreseeable (i.e., probable) future projects (CEQA Guidelines Section 15065(a)(3)). If a lead agency determines that an incremental effect is not "cumulatively considerable," it does not need to consider that effect significant, but it is required to briefly describe its basis for concluding that the incremental effect is not cumulatively considerable (CEQA Guidelines Section 15130(a)).

CEQA Guidelines Section 15130(b) states, "The discussion of cumulative impacts shall reflect the severity of impacts and their likelihood of occurrence, but the discussion need not provide as great [a level of] detail as is provided for the effects attributable to the project alone. The discussion should be guided by standards of practicality and reasonableness, and should focus on the cumulative impact to which the identified other projects contribute rather than the attributes of other projects which do not contribute to the cumulative impact." Section 15130(b) further describes what the discussion of cumulative impacts should include:

- Either: (1) a list of past, present, and probable future projects producing related or cumulative impacts; or (2) a summary of projections contained in an adopted general plan or similar document, or in an adopted or certified environmental document, that described or evaluated conditions contributing to a cumulative impact
- A discussion of the geographic scope of the area affected by the cumulative impact
- A summary of expected environmental effects to be produced by these projects
- Reasonable, feasible options for mitigating or avoiding the project's contribution to any significant cumulative effects

The analysis in this section addresses the cumulative impacts associated with construction and operation of the proposed project. Chapter 6 addresses the cumulative effects associated with growth inducement and the secondary effects of growth resulting from project implementation. Section 4.1 of Chapter 4 describes the overall approach to the assessment of project impacts.

4.15.2 Cumulative Impact Analysis Methodology

The cumulative impact analysis considers the impacts of the project in combination with past projects, projects currently under construction, and probable future projects including: (1) San

Francisco Public Utilities Commission (SFPUC) projects or activities in the project area; and (2) non-SFPUC projects or activities in the project area under the jurisdiction of other local agencies that meet the following criteria:

- The cumulative project and impacts potentially occur within the same geographic location as the project sites
- The cumulative project has or could potentially result in similar impacts as those resulting from the construction and/or operation of the proposed project
- The cumulative project and impacts would occur within the same general timeframe as the proposed project

Analysis of cumulative impacts requires estimation in many cases, because specific quantification of impacts is not always possible, due to variations in the status and timing of projects and environmental conditions that may exist when cumulative projects are developed. The CEQA Guidelines state that the discussion of cumulative impacts should be guided by standards of practicality and reasonableness (CEQA Guidelines, 15130 [b[). As such, the analysis presented below addresses impacts that might compound or interrelate with those of the proposed project.

4.15.3 Cumulative Projects Considered

Table 4.15-1 lists the cumulative projects considered in this analysis. The table presents the planning jurisdictions, a brief description of each project, the potential cumulative impact areas, the estimated construction schedule associated with each cumulative project, the distance of the cumulative project to the project sites, and the project site potentially affected by the cumulative project. The column titled "Potential Cumulative Impact Areas" generally summarizes the anticipated cumulative impacts; site-specific environmental review was not conducted for each listed project. Project information listed in Table 4.15-1 is based on information supplied by the SFPUC, consultations with the Community Development and Public Works/Engineering Departments of San Joaquin and Stanislaus Counties as well as the City of Tracy Community Development Department, and review of available environmental documents and information posted on agency websites.

TABLE 4.15-1
Cumulative Projects Considered

Jurisdiction	Project Title	Project Summary	Potential Cumulative Impact Areas	Estimated Construction Schedule	Approximate Distance to Project Sites	Site Potentially Affected
CCSF (SFPUC)	Thomas Shaft Roadway Improvement Project	The project consists of modifying and improving the existing 1.5-mile Thomas Shaft Road, between Corral Hollow Road and the Thomas Shaft Chlorination Facility. The project would realign or widen some portions of the roadway and improve the roadway surface. Also, as part of the project, an existing temporary concrete water flow structure would be replaced with a 50-foot arch span bridge, one existing culvert would be replaced, and two new culverts installed along the road.	Construction-related traffic on access roads and associated air quality, noise and biological resource impacts	Construction is estimated to occur between August 2008 – January 2009	Approximately 4.4 miles downstream from the Tesla Portal site, and within the Thomas Shaft site	Thomas Shaft
CCSF (SFPUC)	Thomas Shaft Security Upgrades	The existing fence would be modified (made higher, card readers and intrusion alarms installed, and locking mechanism changed) and fencing should be installed around the transformer and the enclosures adjacent to the transformer (across from the Chlorination Building).	Construction-related traffic on access roads and associated air quality, noise and biological resource impacts	Expected to occur 2010 – 2011.	Within the Thomas Shaft site	Thomas Shaft
CCSF (SFPUC)	Thomas Shaft Chlorination Facility Phase 2 Project	The proposed improvements would better meet current operational needs at the existing Thomas Shaft Chlorination Facility. The existing above-ground metal vent stack would be demolished and replaced with a larger 20-foot high 16-foot by 35-foot reinforced concrete vent structure on top of the existing vent shaft. The down-shaft well casing and at-grade shaft cover of Sampling Station No. 1 would be replaced. A new pump assembly would be added to Sampling Station No. 2 that can be lowered into the shaft. Another new pump would be installed within the existing third well casing at the construction shaft. Access ladders, guardrails, and kickboards for three existing hypochloride tanks would be installed. The floor slab in the generator room would be repaired and a new exterior steel staircase	Construction-related traffic on access roads and associated air quality, noise and biological resource impacts	Construction is estimated to occur begin summer of 2008 and should be completed in approximately four to six months.	Within the Thomas Shaft site	Thomas Shaft

TABLE 4.15-1
Cumulative Projects Considered

Jurisdiction	Project Title	Project Summary	Potential Cumulative Impact Areas	Estimated Construction Schedule	Approximate Distance to Project Sites	Site Potentially Affected
		would be installed. Additional ductwork would be added, modifications to the electrical system would be made, and the closed-circuit TV system would be replaced. The underground double containment piping from the existing building to the existing waste liquid storage tank would be replaced. The south fence and automated sliding gate would be replaced, and new pavement would be added within the existing gravel parking area along with a mobile restroom trailer—the waste would be cleaned out by a contractor on a regular basis. A new trench connecting the vent shaft with the construction shaft would contain a 4-inch-diameter below-grade pipe and communication /control lines. The maximum depth of excavation for the trenching would not exceed three-feet. About 120 cubic yards of soil would be excavated for the footing of the vent structure, the maximum depth of which would not exceed 4.5 feet. The spoils from the excavation would be evenly redistributed over the adjacent previously disturbed relocation site.				
CCSF (SFPUC)	San Joaquin Pipeline (SJPL) System	This project is located along the existing SJPL right of way and includes condition assessment and rehabilitation/replacement of a 6.5-mile-long segment of SJPL No. 3 from Oakdale Portal to the west; and a new approximately 11-mile-long pipeline parallel to the existing SJPL System west of the San Joaquin River to Tesla Portal. The project also includes construction of two additional crossover facilities. These improvements would provide the SJPL System the capacity to deliver a flow of 313 mgd with all pipelines in service, and an estimated combined average maintenance flow	Possible overlap of onsite construction activities and staging area. Construction-related traffic on access roads and associated air quality and noise impacts, as well as biological resource impacts	2010-2014	Nearest improvements would occur within the Tesla Portal site	Tesla Portal

TABLE 4.15-1
Cumulative Projects Considered

Jurisdiction	Project Title	Project Summary	Potential Cumulative Impact Areas	Estimated Construction Schedule	Approximate Distance to Project Sites	Site Potentially Affected
		of 271 mgd when one pipeline reach is out of service for planned maintenance, inspection, or emergency repair.				
CCSF (SFPUC)	Rehabilitation of Existing SJPLs	The Rehabilitation of Existing SJPLs Project consists of condition assessment, monitoring, and rehabilitation of the existing SJPLs. The purpose of this project is to establish a program of intensified condition assessment, monitoring, and rehabilitation that will minimize unplanned outages. The detailed condition assessment of the pipelines is ongoing. Although specific rehabilitation measures have not all been identified, a portion of the work has been identified to include a corrosion monitoring system, replacement and installation of cathodic protection, and repair crown crack on SJPL No. 3.	Possible overlap of onsite construction activities; construction-related traffic on access roads and associated air quality and noise impacts, as well as biological resource impacts	2008-2014	Nearest project activities could occur within the Tesla Portal site.	Tesla Portal
City of Tracy	Tracy Gateway PUD	Phased construction of 5.8 million square feet of office, commercial, and retail uses with an anticipated population of 20,000 employees. A multi-story hotel and a golf course are also proposed for the 538-acre development area. The City has not received any development applications to date (11/2007) (City of Tracy, Bell, 2007).	Increased surface runoff and water quality impacts during construction; visual resources, biological resources, air quality, traffic, public services, utilities, and noise	TBD (Some utility, roadway, and other infrastructure improvements could start in spring/ summer of 2008 or 2009); construction of new homes could not occur until 2012 when the current growth ban lifts; some commercial development could occur before then, but it has not yet been determined by the City.	Approximately 10 miles to the northwest of the Tesla Portal site, and approximately 10 miles to the north of the Thomas Shaft site	Tesla Portal and Thomas Shaft

TABLE 4.15-1
Cumulative Projects Considered

Jurisdiction	Project Title	Project Summary	Potential Cumulative Impact Areas	Estimated Construction Schedule	Approximate Distance to Project Sites	Site Potentially Affected
City of Tracy	Tracy Hills Specific Plan	The Tracy Hills Specific Plan area consists of 6,175 acres. Approximately 2,700 fall within the City limits and are planned for a maximum of 5,499 residential units, 6 million square feet of commercial, office, and industrial uses, and approximately 800 acres of neighborhood parks, schools, recreational uses, other open space, roads, and canals. The approximately 3,550 acres located within the City's Sphere of Influence are planned as permanent open space for habitat conservation and managed grazing. Because of the City's Slow Growth Initiative, development permits would not be granted for three to six years from now (11/2007) (City of Tracy, Bell, 2007).	Increased surface runoff and water quality impacts during construction; construction-related traffic impacts on local roads (e.g., Corral Hollow Road) and associated air quality and noise impacts; visual resources biological resources operational traffic, air quality, noise, public services, and utilities impacts	TBD (Some utility, roadway, and other infrastructure improvements could start in spring /summer of 2008 or 2009); construction of new homes could not occur until 2012 when the current growth ban lifts; some commercial development could occur before then, but it has not yet been determined by the City.	Approximately 3.5 miles to the northwest of the Tesla Portal site, and approximately 3.5 miles to the northeast of the Thomas Shaft site	Tesla Portal and Thomas Shaft
City of Tracy	Ellis Specific Plan	The Ellis Specific Plan provides comprehensive land use policy, zoning, and design guidelines for the future development of approximately 320-acres in the City of Tracy. Implementation of the plan would allow a mix of residential, commercial, office/professional, institutional, and recreational uses. The plan would accommodate up to 2,250 residential units; 180,000 square feet of commercial use; approximately 40-acres of parks; and, a 20-acre swim center.	Increased surface runoff and water quality impacts during construction; construction-related traffic impacts on local roads (e.g., Corral Hollow Road) and associated air quality and noise impacts, biological resource impacts, operational traffic, air quality, and noise impacts	TBD (Infrastructure improvements and construction of the 20-acre swim center could start in spring and/or summer of 2009 or 2010); construction of new homes could not occur until 2012 when the current growth ban lifts; some commercial development could occur before then, but it has not yet been determined by the City.	Approximately 4 miles to the northwest of the Tesla Portal site, and approximately 5 miles to the northeast of the Thomas Shaft site	Thomas Shaft and Tesla Portal

TABLE 4.15-1
Cumulative Projects Considered

Jurisdiction	Project Title	Project Summary	Potential Cumulative Impact Areas	Estimated Construction Schedule	Approximate Distance to Project Sites	Site Potentially Affected
San Joaquin County	Corral Hollow Road Improvements Project	The County of San Joaquin Department of Public Works is planning a roadway safety improvement project on Corral Hollow Road, which would install guardrails approximately two miles west of I-580.	Construction-related water quality impacts; traffic impacts on local roads (e.g., Corral Hollow Road) and associated air quality and noise impacts	Construction scheduled to start in July of 2008; anticipated schedule of completion is end of 2008 or early 2009.	Approximately 2 miles northeast of the project site.	Thomas Shaft
San Joaquin County and Stanislaus County	RMC Pacific Vernalis Quarry Mining and Reclamation Project	The project proposes the expansion of an existing quarry that would include sand and gravel extraction and processing of construction aggregate on 688 acres, with permitted active mining for 26 to 60 years on a 659-acre site in San Joaquin County (590 acres) and Stanislaus County (98 acres).	Construction-related traffic impacts on regional roads (e.g., Highway 132) and associated air quality and noise impacts, as well as operational traffic, air quality, and noise impacts	Construction scheduled to start in 2008	Approximately 2.5 miles to the southeast of the Tesla Portal site, and approximately 7 miles to the southeast of the Thomas Shaft site	Tesla Portal
San Joaquin County	Bird Road/Highway 132 Interchange	Replacement of four-way stop with interchange facility at the intersection of Bird Road and Highway 132 to improve operations and increase safety.	Construction-related water quality impacts; traffic impacts on regional roads (e.g., Highway 132) and associated air quality and noise impacts	2008–2009	Approximately 3.5 miles east of the Tesla Portal site, and approximately 10 miles northeast of the Thomas Shaft site	Tesla Portal
Lawrence Livermore National Laboratory	LLNL Site 300 Pipeline Connection	This project proposes to connect to the SFPUC Thomas Shaft water supply through an existing 7000' (length) by 10" (diameter) pipeline that is located along the Thomas Shaft Roadway. The existing connection to the Thomas Shaft and LLNL Site 300 would be opened to flush any existing water and disinfect the pipeline prior to connection. Depending on the quality of the water, LLNL would seek a permit or permits to either discharge the water to Corral Hollow Creek or infiltrate it into the ground. If the water quality does not meet the discharge requirements of the federal Clean Water Act or	Possible biological impacts	2009	Pipeline originates at Thomas Shaft Facility	Thomas Shaft

TABLE 4.15-1
Cumulative Projects Considered

Jurisdiction	Project Title	Project Summary	Potential Cumulative Impact Areas	Estimated Construction Schedule	Approximate Distance to Project Sites	Site Potentially Affected
		California Water Code, the water may be treated prior to discharge or may be disposed at an offsite facility. Any wastes would be disposed of according to federal state and local laws and approved LLNL policies and procedures for hazardous and non-hazardous waste, as appropriate.				
California State Parks	Carnegie State Vehicular Recreational Area Alameda-Tesla Expansion Project	The project would expand the off-highway vehicle (OHV) use at Carnegie State Vehicular Recreational Area (SVRA). In 1998, the state purchased over 3,000 acres west of the current riding area for inclusion in the Carnegie SVRA. This proposal would increase OHV recreational opportunities at Carnegie SVRA, including an extensive multiple use (for example, motorcycles, all terrain vehicles, 4x4 vehicles, sports utility vehicles) trail system, a 4x4 vehicle obstacle course, a day-use staging area, and interpretive and informational facilities. This project may also provide non-OHV recreational opportunities, such as mountain biking, horseback riding, and hiking, provided there is no conflict between these activities and OHV users.	Increased surface runoff and water quality impacts during construction; construction-related traffic impacts on local roads (e.g., Corral Hollow Road) and associated air quality and noise impacts, as well as traffic, air quality, noise, erosion, and biological resource impacts associated with operations	Construction is scheduled to start in May 2009.	Approximately one mile to the west of the Thomas Shaft site, and approximately 5.5 miles southwest of the Tesla Portal site	Thomas Shaft

4.15.4 Impacts

Significance Criteria

The City and County of San Francisco (CCSF) has not formally adopted significance standards for impacts related to cumulative effects, but generally considers that implementation of a proposed project would have significant cumulative impacts if it were to:

- Have impacts that would be individually limited but cumulatively considerable ("cumulatively considerable" means that the incremental effects of a project are significant when viewed in connection with the effects of past, present, and probable future projects)

Project impacts that would be "individually limited" are based on the impact analyses and significance criteria presented in Sections 4.3 through 4.14 for the various environmental resource topics. Following is a discussion of potential cumulative effects for each of the environmental resource topics, including the geographic area of cumulative effect.

Land Use

With respect to land use impacts, the geographic scope of potential cumulative impacts encompasses both project sites and their immediate vicinities, including their construction staging areas. However, major developments in the region are considered when characterizing overall regional land use impacts.

Because the project would not change the general use of either the Tesla Portal or Thomas Shaft sites, and the proposed improvements would be confined to a relatively small portion of each site, with the remainder of each site left as undeveloped open space, neither project construction or operation would substantially alter existing land use patterns. Furthermore, since the project would occur on existing SFPUC lands, which are 0.5 mile away from the nearest established community, the construction of the proposed improvements and their on-going operation would not disrupt established communities.

As indicated in Table 4.15-1, reasonably foreseeable cumulative development in the project area would result in the development of new residential, commercial, office, industrial, and institutional uses, as well as transportation projects (including highway improvements), infrastructure improvements (including utilities and roadways), and quarry expansion. Reasonably foreseeable future development could disrupt established communities and substantially alter existing land use patterns. Table 4.15-1 also identifies several other SFPUC projects that would occur within either the Tesla Portal site, the Thomas Shaft site, or in proximity to either site. These projects in combination with the proposed project could contribute incrementally to cumulative temporary land use disruption during construction (a combination of noise, vibration, dust, traffic congestion, and/or access disruption constitutes a temporary land use disruption).

Due to the relative remote location of both sites, undeveloped nature of the project areas, and the distances of each site from nearby uses, the project in combination with other projects located at

or near either site would not create a cumulative land use impact. Thus, the project would not contribute to cumulative community disruption or alteration of existing land use patterns. Moreover, implementation of SFPUC standard construction measures would ensure that the combined effects of the project and other SFPUC projects at the Tesla Portal and Thomas Shaft sites would result in less than significant land use disruption. Therefore, the project's contribution to cumulative impacts on land use would not be cumulatively considerable.

Visual Quality

With respect to visual quality impacts, the geographic scope of potential cumulative impacts encompasses both project sites and the immediate vicinities, including construction staging areas. Major developments in the region are also considered when characterizing overall regional visual quality impacts.

The proposed improvements at the Thomas Shaft site would not contribute to changes to the viewshed during construction or operation, since the site is not visible from any scenic vistas or scenic roadways; the new UV system would be installed within the existing Chlorination Facility building; the new prefabricated building would be designed to be visually compatible with the existing facility; the closest residence is approximately 1.25 miles northeast of the nearest rural residence; and no additional exterior lighting would be installed at the site.

Improvements proposed for the Tesla Portal site would have a less than significant impact during construction due to the distance of the site from I-580 and the implementation of Standard Construction Measure #10, which would reduce the visibility of staging areas, require the SFPUC to maintain a clean and orderly site, and redirect nighttime lighting away from residential areas during construction. After construction, the proposed improvements at the Tesla Portal site would have less than significant impacts on the visual character and quality of the site, as they would be confined to a small portion of the site with the majority retaining its existing rural visual character and qualities; all the facilities would be of a similar visual scale and character as existing facilities; areas disturbed by construction would be re-vegetated to restore the pre-existing natural vegetative cover; and, few homes have direct views of the site. Post construction at the Tesla Portal site, new buildings would be visible from I-580 (a State Designated Scenic Highway from I-5 to the Alameda County line) and the structures would not be shielded from view by trees or any other vegetation, resulting in a potentially significant impact that could be mitigated to a less than significant level through Mitigation Measure 4.3-5b (landscape screens such as berms or trees). Other proposed improvements at the Tesla Portal site would either not be visible from offsite locations or would not be visually prominent, resulting in less than significant operational impacts on the scenic vista.

The cumulative projects listed in Table 4.15-1 include several major development projects that could substantially affect scenic vistas or resources, alter the visual character of areas within the project vicinity, and introduce new sources of light or glare within the project area. Cumulative development associated with major development projects in Table 4.15-1 would occur in or adjacent to the City of Tracy, and the nearest proposed development project (Tracy Hills) would be approximately 3.5 miles to the northwest of the Tesla Portal site, and approximately 3.5 miles

to the northeast of the Thomas Shaft site. The potential for significant cumulative changes in visual quality, including the introduction of light and glare would be minimized because these development projects are in proximity to the City of Tracy and, therefore, these major development projects would add to the existing urban/developed character of the City of Tracy. Other projects listed in Table 4.15-1 include roadway improvements, improvements or modifications to existing public utility infrastructure or other public facilities, and expansion of a quarry and OHV recreation area. These projects would create a permanent change in the landscape. When combined with cumulative projects identified in Table 4.15-1, the project would not contribute considerably to cumulative visual quality impacts because both sites are located in relatively remote and isolated locations that are not readily visible from many sources and are separated from cumulative development by expanses of undeveloped land that would remain visually unchanged. The project's incremental contribution to cumulative visual quality impacts would not be cumulatively considerable.

Geology, Soils and Seismicity

The geographic scope of potential cumulative geologic and seismic impacts incorporates the project sites and immediate vicinities. Geologic and seismic impacts are generally site specific and depend on local geologic and soil conditions**.**

As discussed in Section 4.4, Geology, Soils and Seismicity, native soils found within the project sites are potentially corrosive or expansive, exhibiting a high shrink/swell potential and may exhibit a high risk of corrosion to concrete and uncoated steel, resulting in a potentially significant impact. None of the projects listed on Table 4.15-1 that would occur at another location could contribute cumulatively to the potential local corrosive or expansive soil hazard (or any other geologic hazard). However, the SJPL System Project and the Rehabilitation of Existing SJPLs project would occur at the Tesla Portal site during the same time period as the proposed improvements at that location and would both involve rehabilitation/replacement of pipelines. Consequently, these two projects in combination with the improvements proposed at the Tesla Portal site could result in cumulative corrosion and expansive soil hazard impacts. With implementation of Mitigation Measure 4.4-9, which would characterize the extent of expansive and corrosive soils and incorporate the results of the investigation into the final project design, the project impact would be less than significant and the project would not contribute to any cumulative impact related to corrosive or expansive soil hazard. Furthermore, the project would not affect the availability of known or locally important mineral resources individually. Consequently it could not incrementally contribute to the loss of the availability of known or locally important mineral resources.

As described in the Project Description, the proposed project includes an upgrade to the existing disinfection facilities at the Tesla Portal Hypochlorite Station to meet current seismic, safety/fire, and building code standards to help protect the water system from the effects of earthquakes and other hazards. In addition, several cumulative SFPUC projects would also contribute to improving the seismic safety of water system facilities, including pipeline repairs and replacements. These improvements in combination with the project work at the Tesla Portal site

would contribute to beneficial cumulative effects related to the safety of the regional water system during a seismic event**.**

Hydrology and Water Quality

The geographic scope of potential cumulative hydrology and water quality impacts encompasses adjacent undeveloped areas, as the surface runoff from both sites currently drains to open areas adjacent to paved surfaces on each site.

Although less than significant, construction activities at the Tesla Portal could affect the artificial wetland and unnamed ephemeral drainage located on the site. There would be a relatively small area of impact (disturbed areas) at Tesla Portal. Work conducted at the site would be done in compliance with NPDES General Permit requirements, including preparation of a SWPPP, and SFPUC Construction Measures #3 and #10 would be implemented, which would incorporate erosion control measures as necessary and return the site to its general pre-construction condition. Construction and tie-in of the new SJPL facilities during the regularly scheduled Hetch Hetchy shutdown of SJPL pipelines would preclude discharges of large volumes of water.

The cumulative projects listed in Table 4.15-1 have the potential to affect hydrology and water quality. Table 4.15-1 identified several development projects which would increase impervious areas in the region and have the potential to increase surface runoff. Operational activities associated with the Carnegie State Vehicular Recreational Area Alameda-Tesla Expansion Project and construction activities associated with several other cumulative projects have the potential to increase erosion and impact water quality. However, all of the projects would be required to comply with federal (Clean Water Act [CWA]), state (National Pollutant Discharge Elimination System [NPDES]) and local (municipal stormwater regulations) permitting requirements.

NPDES and other discharge regulations are designed to protect water quality on a regional basis and incorporate measures to protect beneficial uses of water bodies based on overall consideration of past, present, and future conditions within the region. The regulations require that projects implement best management practices (BMPs) for erosion control and construction-related discharges, and corrective actions in the event that permit exceedances occur during construction. BMPs are designed to reduce impacts associated with increased erosion, sedimentation, and pollutant discharges to the environment during construction. Several of the cumulative projects in Table 4.15-1 were identified as SFPUC projects, including the Thomas Shaft Roadway Improvement Project, Thomas Shaft Security Upgrades, Thomas Shaft Chlorination Facility Phase 2 Project, the San Joaquin Pipeline (SJPL) System, and the Rehabilitation of Existing SJPLs. The SFPUC projects must also comply with the SFPUC Standard Construction Measures that complement the NPDES and General Permit provisions. Therefore, the project's contribution to cumulative impacts on hydrology and water quality would not be cumulatively considerable.

Biological Resources

The geographic scope for potential cumulative impacts on biological resources is the grassland areas adjacent to the project sites and the project sites of the other cumulative projects listed in Table 4.15-1.

Project construction activities would result in temporary degradation of the bed and bank of the ephemeral drainage located at the Tesla Portal site, as well as sedimentation and erosion of its down stream portions; less than 0.001 acre of the ephemeral drainage would be impacted. Of the projects identified in Table 4.15-1, only the SFPUC SJPL System and Rehabilitation of Existing SJPL projects would have the ability to affect the ephemeral drainage. The project's impacts on the ephemeral drainage combined with the ephemeral drainage impacts of these two projects would be potentially significant. Mitigation Measures 4.6-1a and 4.6-1b require participation in the San Joaquin County Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) for the replacement of habitat that would be equal to that of the temporary loss of <0.001 acre of ephemeral drainage, as well as the implementation of best management practices (i.e., fencing, erosion control and re-contouring of the impact area). As such, the project's mitigated impact on the ephemeral drainage is less than significant. Due to the minor amount of the drainage that would be affected by the project, and implementation of the measures noted above, the project's contribution to cumulative impacts on the ephemeral drainage would not be cumulatively considerable (less than significant).

Construction staging and other construction-related activities at the Tesla Portal project site could result in the temporary impacts on 11.716 acres of California annual grasslands and 0.846 acre of ruderal/disturbed habitat. Construction at the Thomas Shaft site would result in temporary impacts on 0.110-acre of ruderal/disturbed habitat. In addition, the proposed project would result in the permanent loss of approximately 3.2 acres of California annual grassland at the Tesla Portal site and 0.008-acre ruderal/disturbed habitat at the Thomas Shaft site.

Due to their relative closeness to the project sites, the projects identified in Table 4.15-1 are in generally similar settings as the Tesla Portal and the Thomas Shaft sites, and as such would be expected to have construction activities that could result in impacts on California annual grasslands. In addition, the development associated with many of these projects (residential units, commercial spaces, offices, and industrial developments) would also likely result in the permanent loss of California annual grasslands. Impacts on California annual grasslands would contribute to the degradation of natural habitat in the region and could result in the permanent loss of habitat. The project's temporary impacts on California annual grasslands combined with the loss of California annual grasslands of other projects identified in Table 4.15-1 would be potentially significant. Mitigation Measures 4.6-1a, 4.6-1b, and 4.6-2 (participation in the SJMSCP, implement Best Management Practices, and returning the site to pre-project conditions) would reduce the project's potential temporary construction impacts to less than significant. Implementation of these measures would substantially reduce the project's contribution to cumulative impacts and would not be cumulatively considerable.

Permanent loss of California annual grasslands would contribute incrementally to the statewide loss of this type of habitat. As such, the impact of permanent loss of California annual grasslands from the proposed project combined with the permanent loss of California annual grasslands of other projects identified in Table 4.15-1 would be potentially significant. The project would result in the permanent loss of approximately 3.2 acres of California annual grassland, which is minor in comparison to the permanent loss of California annual grasslands that could be expected from other projects listed in Table 4.15-1. Loss of California annual grasslands resulting from project implementation would be less than significant given the abundance of similar grassland habitats in the immediate area and adjacent to the project sites and the relatively small amount of habitat loss. In addition, the proposed project would not substantially degrade the function of this habitat type in the local context of the project sites, and would not result in severe habitat fragmentation. Therefore, the project's conversion of 3.2 acres of California annual grassland would not have a cumulatively considerable contribution to the statewide loss of this type of habitat.

Project construction could result in temporary loss of foraging and/or breeding habitat for some or all of the special status species known to occur, or with potential habitat present at the project sites. These species include: California Red-Legged Frog, California Tiger Salamander, San Joaquin Whipsnake, California Horned Lizard, San Joaquin Kit Fox, San Joaquin Pocket Mouse, Pallid bat, Townsend bat, Mastiff bat, Burrowing owl, Swainson’s Hawk, White-tailed Kite, Ferruginous Hawk, Golden Eagle, Prairie Falcon, Northern Harrier, Tricolored Blackbird, and California Horned Lark.

The projects identified in Table 4.15-1 are located primarily within five miles of the project sites (ten miles distance at maximum) in similar settings and would be expected to have similar special status species foraging and breeding habitat as the proposed project. Consequently, construction of many of the projects identified in Table 4.15-1 could result in temporary loss of foraging and/or breeding habitat for some or all of the special status species known to occur or with potential habitat present at the project sites. As such, the impact of temporary loss of special status species foraging and/or breeding habitat from the proposed project combined with the temporary loss of special status species foraging and/or breeding habitat of other projects identified in Table 4.15-1 would be potentially significant. The SFPUC will implement Mitigation Measure 4.6-1a, which requires participation in the SJMSCP and requires the implementation of incidental take mitigation measures (ITMMs), to mitigate for impacts on special-status species, thus reducing impacts on biological resources to a less than significant level. As such, construction of the proposed project would not have a cumulatively considerable contribution to temporary loss of foraging and/or breeding habitat for some or all of the special status species known to occur, or with potential habitat present at the project sites.

Additionally, operation of the proposed project would result in the permanent reduction of special-status wildlife foraging and/or breeding habitat. In total, the proposed project (Tesla Portal and Thomas Shaft) would convert 3.2 acres of California annual grasslands. The conversion of this habitat would result in the permanent loss of breeding and/or foraging habitat for all the 18 special-status wildlife species (identified above) with the potential to be present on either project site.

Permanent conversion of special species habitat would contribute incrementally to the statewide loss of special species habitat. As such, the impact of the project's permanent conversion of habitat for the 18 special status species identified above combined with the permanent conversion of this type of habitat resulting from other projects identified in Table 4.15-1, would be potentially significant. The project would result in the permanent conversion of approximately 3.2 acres of special species habitat. However, this amount is minor in comparison to the permanent loss of special species habitat that could be expected from other projects listed in Table 4.15-1. Loss of special species habitat resulting from project implementation would be less than significant given the abundance of higher quality special-status species habitat in the proximity of the proposed project sites, as well as the relatively small size of the proposed project footprints. In addition, the SFPUC would participate in the SJMSCP (Mitigation Measure 4.6-1a). Therefore, the project's conversion of 3.2 acres of potential special species habitat would not have a cumulatively considerable contribution to the statewide conversion of this type of habitat.

Operation of the proposed project would result in the permanent loss of 0.3 acre of artificial wetland when water from the analyzer equipment at Tesla Portal is no longer discharged to the artificial wetland area. Wetland functions and values (i.e., the only year-round source of water in the project area and surrounding valley bottom) would be lost, resulting in substantial degradation or reduction of habitat values for dependent plant and wildlife species. Cumulative loss of wetlands could result due to development of residential units, commercial spaces, offices, and industrial developments (identified in Table 4.15-1). As such, the impact of wetlands loss from the proposed project combined with the potential for loss of wetlands due to other projects identified in Table 4.15-1 would be potentially significant. Mitigation Measure 4.6-1a requires participation in the SJMSCP for the replacement of the artificial wetland habitat that would be permanently lost. Implementation of this mitigation measure would substantially reduce the project’s contribution to permanent wetland loss to a less than cumulatively considerable level and project operation would not have a cumulatively considerable contribution to regional permanent wetland loss.

Cultural Resources

The geographic scope of potential cumulative impacts on cultural resources encompasses the project sites and their immediate vicinities, and other cumulative projects near the project sites.

Project construction activities would exceed historic ground disturbance by six feet at the Tesla Portal site. This could result in disturbance of native sediments and bedrock containing paleontologically sensitive geologic units within the Tesla Portal area of potential effect (APE), resulting in the potentially significant, but mitigable impact of disturbing or destroying paleontological resources. Due to their relative closeness to the Tesla Portal site, the projects identified in Table 4.15-1 are in generally similar geologic settings as the Tesla Portal site, and as such, their construction has the potential to disturb or destroy the same paleontologically sensitive geologic units as the project would, potentially disturbing or destroying paleontological resources. The project's impacts on paleontological resources combined with the paleontological resource impacts of projects identified in Table 4.15-1 would be potentially significant. Mitigation Measures 4.7-1a and 4.7-1b require monitoring construction, relocating construction

work away from the area if a paleontological resource is identified, and having the site inspected by a qualified paleontologist. As such, the project's mitigated impact on the paleontological resources would be less than significant. Construction of the proposed project would not have a cumulatively considerable contribution to disturbance or loss of paleontological resources.

The project has the potential to encounter unanticipated subsurface archaeological deposits or human remains at either site because their subsurface presence cannot be conclusively ruled out. This also holds true for projects identified in Table 4.15-1. The project's impacts on unanticipated subsurface archaeological deposits combined with the archaeological resource impacts of projects identified in Table 4.15-1 could be potentially significant. Mitigation Measure 4.7-2a requires all work to halt within 100 feet of a find until a qualified archaeologist can evaluate the find and make recommendations. Measure 4.7-2b requires that the County Coroner notify the Native American Heritage Commission within 24 hours if human remains of Native American origin are encountered, and requires that their treatment conforms with State laws. Implementation of these mitigation measures would reduce the project's contribution to a level that is not cumulatively considerable (less than significant).

At the Tesla Portal site, the Southwest Valve House and the San Joaquin Pipelines (SJPLs) Nos. 1 and 2 are potentially eligible historic architectural resources that could be directly or indirectly affected by project construction. Project construction activities would take place approximately 25 feet from the Southwest Valve House, and a small portion (300 feet) of the approximately 47.5 mile long SJPLs Nos. 1 and 2 would be modified by the project. These construction activities could potentially significant impacts on these historic resources.

Of the projects identified in Table 4.15-1, two SFPUC projects (SJPL System and Rehabilitation of Existing SJPLs) have the potential to also affect these resources during construction. The project's impacts in combination with the two SFPUC cumulative projects could be potentially significant. Project implementation of Mitigation Measure 4.7-3 (Architectural Resources Protection Plan) would ensure protection of identified resources at the Tesla Portal site during construction activities and would reduce impacts to a less-than-significant level. Given that the project impacts would be relatively minor and would be fully mitigated, the project's contribution to cumulative impacts on historic architectural resources would not be cumulatively considerable (less than significant).

Traffic, Transportation, and Circulation

The geographic scope of potential cumulative traffic impacts includes regional facilities (e.g., highways and freeways) and local roads providing access to the project sites.

The impact of short-term cumulative traffic increases from the project construction combined with cumulative traffic increases of other projects associated with construction and operation identified in Table 4.15-1 would be potentially significant. Construction of the project in combination with projects listed in Table 4.15-1 could result in short-term cumulative traffic increases, particularly when travel routes of individual drivers utilize roadways affected by other projects listed in Table 4.15-1. The project's contribution to cumulative construction-related

impacts would be temporary, and would occur during the project construction period (2009 to 2011). Cumulative impacts on regional roads would include increased travel times, although the extent and duration of delay would vary depending on individual driver origins and destinations, time of travel, and use of alternate routes. Localized cumulative construction-related traffic impacts could occur as a result of: 1) cumulative projects that generate increased traffic at the same time on the same roads as the proposed project, causing increased congestion and delays; and 2) infrastructure projects in roads used by project construction workers and trucks, which could delay project-generated vehicles past the work zones of the other projects. Consequently, development of the project in conjunction with other cumulative developments in the project area could result in cumulative increases in construction-related traffic on regional roadways (e.g., SR 132 and I-580). Furthermore, construction of the project in combination with other SFPUC projects could result in cumulative increases in traffic on local roadways providing access to both the Tesla Portal site and Thomas Shaft site. Implementation of SFPUC Construction Measure #5, in combination with implementation of Mitigation Measures 4.15-1a through 4.15-1c would reduce the project's contribution to region-wide and localized cumulative traffic impacts to a less-than-significant level. These mitigation measures require the SFPUC to identify a construction coordinator responsible for coordinating project-specific traffic control plans, the development of a San Joaquin Regional Traffic Control Plan to coordinate project-specific traffic control plans developed for individual WSIP projects in the San Joaquin Region, and coordinate with other agencies, as appropriate. With implementation of these measures, the project's contribution to cumulative traffic impacts would not be cumulatively considerable.

The project would have minor long-term increases in traffic generated by the addition of two new full time equivalent (FTE) employees and additional maintenance, operation, and deliveries to and from the Tesla Portal site, for a total of seven additional round-trips per day at most (two round-trips per day for the two new employees and four maintenance, operation and delivery related round trips); these additional trips are not significant. The Thomas Shaft site would not generate any new vehicle trips, resulting in no long-term traffic impacts associated with this site. Other cumulative development projects listed in Table 4.15-1 would result in greater long-term cumulative traffic increases generated by the development of new residential units, as well as commercial, office, industrial, and institutional uses. The project-related increases in operational traffic would not likely be discernible from future background increases in traffic. Because this increase in vehicle trips on the roadway network would be minimal, the project's contribution to cumulative traffic increases during project operation would not be cumulatively considerable.

Air Quality

The relevant geographical area for cumulative air quality impacts would be the San Joaquin Valley Air Basin (SJVAB) when analyzing regional impacts, and haul routes and traffic roadways/intersections when analyzing localized impacts. The San Joaquin Valley Air Pollution Control District (SJVAPCD) recommends evaluating the following for cumulative air quality impacts:

- Regional
  - Cumulative ozone impacts (NO_X and ROG)

  - Cumulative PM_{10} impacts
- Local
  - Cumulative CO impacts
  - Cumulative hazardous air pollutant impacts, using ,diesel particulate matter (DPM) as a measure for evaluation

Construction of the proposed project would temporarily generate emissions and contribute to both regional (NO_X, ROG, and PM_{10}) and local (CO and DPM) air impacts. Many of the projects identified in Table 4.15-1 would have construction activities overlapping with the project's construction activities. As such, the impact of construction emissions from the proposed project combined with the construction emissions of other projects identified in Table 4.15-1 would be potentially significant.

Implementation of Mitigation Measures 4.9-1a and 4.9-1b (incorporate SJVAPCD recommended fugitive dust and exhaust mitigation, including enhanced measures, into project construction) would reduce construction emission impacts from the proposed project to a less than significant level. Therefore, construction of the project would not have a cumulatively considerable contribution to regional (NO_X, ROG, and PM_{10}) cumulative emissions.

Construction of the project would generate local CO and DPM emissions. These emissions would be generated primarily from equipment exhaust, employee vehicles, and construction trucks and would be mitigated in accordance with Mitigation Measure 4.9-1b to less than significant. DPM emissions resulting from the proposed project would be less than significant based on traffic volumes, duration, and the distant location of receptors. As such, construction of the proposed project would not have a cumulatively considerable contribution to local CO and DPM cumulative emissions.

As detailed in Section 4.9, operational emission increases from the project are expected to be minor compared to existing conditions and are less than significant. The increases in operational air pollutant emissions from the identified cumulative projects would largely result from regional traffic increases. The proposed project would generate minor vehicle emissions, in addition to minor emissions from the generators and tanks. As such, operation of the proposed project would not have a cumulatively considerable contribution to regional (NO_X, ROG, and PM_{10}) cumulative emissions.

Operation of the proposed project would also generate local CO and DPM emissions. CO and DPM emissions would be generated from the programmatic testing and operation of emergency generators and from increased vehicles trips. As detailed in Section 4.9, operational emission increases (including traffic trips) from the proposed are expected to be minor compared to existing conditions and are less than significant. Therefore, operational vehicle and generator emissions would not have a cumulatively considerable contribution to local (CO, and DPM) cumulative emissions.

Greenhouse Gas (GHG) Emissions

The current statewide annual net GHG inventory is estimated at 479.74 million metric tons of CO_2e (CARB, 2007b). CARB has identified 427 million metric tons of CO_2e as the total statewide greenhouse gas 1990 emissions level and, therefore, the 2020 emissions limit. The limit is a cumulative statewide limit, not a sector or facility specific limit (CARB, 2007a). Therefore, the state's goals are to reduce GHG emissions by 52.74 million metric tons of CO_2e by the year 2020.

The proposed project consists of improvements to existing water system operations and would result in few new operational activities associated with GHG emission increases. GHG emissions from the proposed project would be generated from construction, operations, and secondary operational increases in GHG emissions resulting from electricity generation. The proposed project's emissions would overlap with similar sources of GHG emissions from other cumulative projects. The increase in GHG emissions during project construction and operation would be minimal in comparison to statewide totals.

The project's reasonable worst-case annual construction emissions of GHG are estimated at 5,289 metric tons of CO_2e per year, which represents only 0.0011 percent of the statewide total.

The proposed project would also result in secondary operational increases in GHG emissions as a result of electricity generated to meet the project's increase in energy demand. Although electricity for the proposed project would be derived primarily from hydroelectric sources, power would need to be purchased from other sources when less hydroelectric power is available, particularly during the summer and fall months. Power generation is regional in nature and could occur outside the SJVAB or outside of California. Therefore, the project's incremental increase in power demand during project operations (the portion that is not from hydroelectric sources) would indirectly serve to sustain rather than reduce current GHG emissions.

A very minor amount of GHG emissions (relative to statewide totals) would be emitted during construction and operation of the proposed project. Furthermore, with compliance with federal and state mobile and stationary source regulations, continuing compliance with federal and state GHG regulations (including CARB's Early Action Measures and the CEC's greenhouse gases emission performance standard for local, public owned electric utilities when they become effective), and implementation of GHG reduction actions by the City and County of San Francisco and SFPUC, the project would not conflict with the state goal of reducing GHG emissions in California to 1990 levels by 2020. Therefore, the project's contribution to GHG emissions would not be cumulatively considerable.

Noise and Vibration

The geographic scope of potential cumulative noise impacts encompasses the project sites and their immediate vicinities as well as areas adjacent to the project site's access and haul routes.

The analysis in Section 4.10 concluded that, at the Tesla Portal site, the proposed project would result in a short-term, temporary increase in the ambient noise level during construction but that

impacts are considered less than significant at offsite noise-sensitive receptors. Construction noise from the other SFPUC projects nearby the Tesla Portal site (including the SJPL pipeline system and rehabilitation of the existing SJPLs) could potentially result in a temporary cumulative increase in noise levels at on and offsite receptors. However, even if construction activities were occurring at the same time, noise levels would only increase by 3 dBA. Based on the distance from the cumulative construction activities, sound levels at the community of Chrisman and the residence to the southeast would average 58 dBA, and would average 68 dBA at the uninhabited ranch structures to the west. These levels would be below the 70 dBA daytime speech interference criterion and the 60 dBA nighttime sleep interference criterion at residences; therefore, the project would not contribute considerably to cumulative construction noise impacts at offsite receptors. There could be significant noise impacts at the onsite caretaker's residence. These impacts would be reduced to less than significant by Mitigation Measure 4.10-1, which requires the caretaker's residence be vacated during construction activities that would exceed 70 dBA during the daytime or 60 dBA during the nighttime. Construction activities from the other SFPUC projects would be required to implement the same mitigation measure to avoid cumulative impacts.

The SFPUC Thomas Shaft Roadway Improvement Project and the Thomas Shaft Chlorination Facility Phase 2 projects would both be completed prior to construction of the proposed project. It is possible that six months of noise-generating construction activity at the Thomas Shaft site would occur simultaneously with construction associated with the Carnegie State Vehicular Recreational Area Alameda-Tesla Expansion Project and with the LLNL Site 300 Pipeline Connection project. However, the Carnegie State Vehicular Recreational Area is one mile west of the Thomas Shaft site. The nearest sensitive receptor is a rural residence located about 1.25 miles to the northeast of the Thomas Shaft site, and is separated from the Thomas Shaft site by hills. Given the distance and topography between the Carnegie State Vehicular Recreational Area Alameda-Tesla Expansion Project and the Thomas Shaft site, the project would not contribute considerably to cumulative noise impacts at the Thomas Shaft site.

The roadways that would be part of the common haul route for the Tesla Portal site would be West Vernalis Road and Chrisman Road, while the common haul route for the Thomas Shaft site would be Corral Hollow Road. Cumulative traffic increases on I-580 and SR 132 would not likely alter noise levels significantly along these routes (I-580 and SR 132), given the high ambient noise levels that typically occur along these types of roadways. Because existing and existing plus project noise levels at 50 feet from the centerline of the roadways were calculated to be less than 65 dBA CNEL, noise levels at actual receptors farther away from the road would also be less than the 65 dBA CNEL criterion. Therefore, unless truck traffic associated with the other projects (including SFPUC) is extremely high, (three to four times over the existing levels), it is unlikely that cumulative noise impacts from construction traffic at sensitive receptors would occur.

Public Services and Utilities

The geographic scope of potential cumulative public services and utilities impacts encompasses the project sites, their immediate vicinities, and the service areas of regional service/utility providers.

The tie-in of new facilities at the Tesla Portal site would occur during a regularly scheduled maintenance shutdown between January and February 2010, and would not interrupt service to SFPUC water customers, who would continue to be served by other system sources. Construction of facilities at the Thomas Shaft site would not require any shutdown. Other SFPUC projects identified in Table 4.15-1 could require tie-ins to the SFPUC water supply system. Like the project, these projects would also occur during a regularly scheduled maintenance shutdown, resulting in uninterrupted water service to SFPUC customers. Thus, the project and other SFPUC projects would not contribute to cumulative disruptions in water service for SFPUC customers.

Project construction and operation would generate a minimal amount of solid waste, and the project would not substantially affect the total existing landfill capacity in the San Joaquin region. The construction and operation of other cumulative projects identified in Table 4.15-1 would also generate solid waste; it is anticipated that these projects would be expected to reduce cumulative solid waste impacts through project-specific mitigation requirements. There are three landfills permitted to accept construction and demolition waste in the project vicinity with sufficient capacity that would not be affected by the construction and operation of the project in combination with projects listed in Table 4.15-1. Therefore, the project's contribution to cumulative landfill capacity demand would not be cumulatively considerable (less than significant).

During project operation, the increase in the number of onsite employees would be minimal (two new employees at the Tesla Portal site and no new employees at the Thomas Shaft site), resulting in a minimal increase in the demand for potable water and a minimal increase in the generation of wastewater at the Tesla Portal site. Of the reasonably foreseeable projects listed in Table 4.15-1, the Tracy Gateway PUD, Tracy Hills Specific Plan, and Ellis Specific Plan would require additional water supplies and result in increased wastewater generation. The additional need for water supply generated by these projects may not be able to be reduced to a less than significant level, in which case these cumulative projects could result in cumulatively or individually significant impacts on water supply in the San Joaquin Valley region. The project would not contribute considerably to this cumulative impact, due to its comparatively minor increase in potable water demand. As such, the proposed project would not have a cumulatively considerable contribution to potable water demand. The wastewater generated by the project would be handled onsite by a new proposed septic tank and leachfield at the Tesla Portal site and would not have a cumulatively considerable contribution to wastewater generation.

Agricultural Resources

The geographic scope of potential cumulative agricultural resources impacts encompasses the project sites and their immediate vicinities. However, major developments in non-urban areas are considered when evaluating cumulative regional impacts on agricultural resources.

As indicated in Table 4.15-1, reasonably foreseeable cumulative development in the project area includes new residential, commercial, office, industrial, and institutional uses, as well as transportation projects (highway and roadway improvements), infrastructure improvements (including utilities), and quarry expansion. Cumulative projects involving improvements or

modifications to transportation projects or infrastructure projects could convert some agricultural land, but may not preclude agricultural activity. Various mitigation measures (payment of fees or establishment of offsite agricultural lands in perpetuity) could compensate for such impacts. However, development projects such as the Tracy Gateway PUD, Tracy Hills Specific Plan, Ellis Specific Plan, and the RMC Pacific Vernalis Quarry Mining and Reclamation Project could result in the loss of agricultural land and/or conflict with agricultural zoning or Williamson Act contracts. These projects may not be able to sufficiently mitigate such impacts and, therefore, cumulatively significant impacts on agricultural resources in the project area could occur.

The proposed project would not result in the conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural use; preclude agricultural activities on the undeveloped portion of either site; conflict with Williamson Act contracts; disrupt access to actively farmed parcels; or conflict with zoning for agricultural use. The project is considered an essential public facility, which is allowed under the agricultural zoning designation. As such, the project could not contribute to the cumulative loss of agricultural land.

Hazards

The geographic scope of impacts associated with hazards and hazardous materials encompasses the project sites and their immediate vicinities.

During construction, the proposed project has the potential to encounter hazardous materials in soil and groundwater, accidentally release hazardous materials such as motor fuels, oil, solvents, and lubricants, start a wildfire, impede access for emergency response vehicles, and interfere with an emergency response plan or emergency evacuation plan. Due to the site-specific nature of hazardous materials impacts, only those projects listed in Table 4.15-1 that would occur at or adjacent to the project site, including the SFPUC's SJPL System Project and the SFPUC's Rehabilitation of the Existing SJPL Project, could result in similar hazards and hazardous materials impacts as the project.

The Phase I ESA (AGS, 2007) determined that the likelihood that contaminated soil or groundwater would be encountered during construction of the proposed project at the Tesla Portal site is low. Due to the small scale of current and historic operations at the Thomas Shaft site, its remote location, and the limited scope of proposed improvements and excavation, the likelihood that contaminated soil or groundwater would be encountered during construction at the Thomas Shaft site was also determined to be low. Further, the project would implement SFPUC Construction Measure #7 for hazardous materials, which requires that a site assessment be conducted by a qualified environmental professional no more than three months before construction, and that a contingency plan be prepared identifying measures to be taken should unanticipated contamination be identified during construction. Moreover, the potential that an accidental release would occur at both sites during construction would be reduced by the use of standard operating procedures for the safe storage and use of hazardous materials in compliance with state and federal occupational safety and health codes and regulations.

In addition, the project would comply with SFPUC Construction Measure #3 for water quality, which requires the implementation of erosion control measures, including preparation and implementation of a SWPPP as required by the RWQCB. The project would also comply with regulations governing the use of construction equipment in fire prone areas that are designed to minimize the risk of wildland fires during construction activity in accordance with the Public Resources Code. Project construction would not require the use of public roadways for construction staging and equipment parking. Additionally, no lane or road closures are anticipated. Thus, it is not likely that project construction activities could impede access for emergency response vehicles, interfere with an emergency response plan or emergency evacuation plan. In addition, SFPUC Construction Measure #5, which includes preparation and implementation of a traffic control plan, would be implemented as part of the project to minimize impacts on traffic flow.

Consequently, with compliance with applicable laws and regulations and implementation of SFPUC standard construction measures, the project would result in less than significant hazards and hazardous materials impacts. The construction-related hazards and hazardous materials impacts of the SFPUC's SJPL System Project and the SFPUC's Rehabilitation of the Existing SJPL Project would be anticipated to be reduced to a less-than-significant level as a result of compliance with applicable laws and regulations and implementation of SFPUC standard construction measures, similar to the proposed project. Therefore, the project would not have a cumulatively considerable contribution to hazards and hazardous materials impacts.

The expansion of operations at both project sites would increase the number and quantities of hazardous materials used onsite and thus, would increase the potential for chemical spillage during normal operations due to equipment malfunction or operator error, or be caused by natural hazards, such as seismic events. Such events and accidental chemical release could cause health effects to workers, and less likely, to persons outside the facility fence lines. Releases also could cause adverse environmental effects. Potential impacts related to accidental releases of chemicals stored at the water treatment facilities would be site-specific and not additive. Compliance with hazardous materials regulations (including preparation or updating of hazardous materials business plans) would ensure that site-specific impacts are less than significant. Due to the site-specific nature of these impacts, compliance with applicable laws and regulations, and implementation of SFPUC construction measures and mitigation measures identified in Section 4.13, there would be no potential for region-wide or cumulative effects related to the exposure to hazardous materials during operations at both project sites.

Energy Resources

The geographic scope of impacts associated with energy resources encompasses the project sites, their immediate vicinities, and the SFPUC facilities in the SFPUC Power Enterprise's San Joaquin Region.

- The SFPUC estimates that, in total, the proposed improvements at the Tesla Portal site would require the use of approximately 6,000,000 kWh per year, an increase from the existing annual consumption of 175,000 kWh. Operation of project facilities at Thomas Shaft would result in an

annual energy demand of 110,800 kWh, an increase from its current average annual consumption of 70,800 kWh. The additional energy demand would represent roughly 13 percent of the regional water system's current annual energy use of 44 million kWh per year. Additionally, the energy use by the regional water system is a fraction (less than 3 percent) of the long-term annual average energy production of the Hetch Hetchy system, and would remain at approximately 3 percent, including the project's increased operational energy use.

The operation of other SFPUC projects identified in Table 4.15-1 would not substantially increase energy use in the SFPUC Power Enterprise's San Joaquin Region during operation, because, in general, they are non-energy-intensive improvements to the water system, upgrades related to energy efficiency improvements, or improvements to facility electrical systems. However, the project would have a significant contribution to energy consumption in the SFPUC Power Enterprise's San Joaquin Region. Although the project would primarily receive hydroelectric power from the SFPUC Power Enterprise during the fall and summer months when power generation under the Hetch Hetchy system is reduced, less hydroelectric power would be available and PG&E would supplement power supplies. The project's increase in power use could result in a higher reliance on nonrenewable energy resources during the fall and summer months. Other projects listed in Table 4.15-1 would also rely on PG&E for power during the fall and summer months. As such, the impact of nonrenewable energy consumption during the fall and summer months from the proposed project combined with the nonrenewable energy consumption of other projects identified in Table 4.15-1 would be potentially significant.

- Mitigation Measure 4.14-1 requires energy efficiency measures consistent with the California Energy Action Plan II priorities to be undertaken at both sites. Mitigation Measure 4.14-1 also requires preparation of a repair and maintenance plan for each facility to minimize power use and include the use of renewable energy at the Tesla Treatment Facility. SFPUC would also consider methods for reducing the carbon footprint at each site by requiring review of the final design by the Power Enterprise Energy Efficiency Group, ensuring that any features that would improve energy sustainability are incorporated, as feasible, into the design. SFPUC would also seek to reduce its carbon footprint by incorporating the use of energy efficient lighting, heating, ventilation, and air conditioning (HAVC) systems at each site. Additional specific measures would be undertaken at the Tesla Portal site, such as the incorporation of efficiency measures in the Draft Design Criteria manual for the Tesla Treatment Facility, which would require improvements to meet and/or exceed Title 24 energy efficiency standards by a minimum of five percent.[1] The SFPUC may consider the use of solar power at the Tesla Portal site in the future; however, solar panels are not currently proposed as part of the project and if solar panels were installed at the Tesla Portal site, they would be added after completion of all construction activities at the site. As such, operational energy consumption from the project, with Mitigation Measure 4.14-1 and additional measures to be undertaken by the SFPUC, would be less than significant. Furthermore, any additional power the project may need (above hydroelectric power provided by the SFPUC) during the fall and summer months, when hydroelectric power is reduced, would be negligible and would be purchased from PG&E or other

[1] This minimum five percent reduction in energy use includes lighting systems, which would also meet the recommendations of the Illuminating Engineering Society Handbook.

power generators. Operation of the proposed project would not have a cumulatively considerable contribution to cumulative consumption of nonrenewable energy supplies.

CHAPTER 5
Mitigation Measures

5.1 Introduction

This chapter describes the proposed mitigation measures for the significant and potentially significant environmental impacts identified in Chapter 4, Environmental Setting and Impacts. These measures are designed to be feasible and to ensure that project impacts are avoided or reduced to a less-than-significant level. The SFPUC has adopted Standard Construction Measures (refer to Chapter 3.0, Project Description) that would be implemented as part of the proposed project. If, with implementation of the Standard Construction Measures, the project impact is less than significant, no mitigation measures are identified.

Chapter 4 identifies the level of significance for project impacts. Determinations are one of the following: N/A (not applicable, or no impact), LS (Less than Significant, no mitigation required), and PSM (Potentially Significant Mitigable, impacts can be mitigated to less than significant). The significance determinations are based on the potential effects of the proposed project as they relate to the significance criteria listed in Chapter 4, with consideration of the SFPUC Standard Construction Measures and regulatory requirements. Mitigation measures are identified for impacts determined to be PSM, to the extent that feasible mitigation would be available.

- As previously discussed in Section 1.2, the proposed project is a component of the SFPUC's Water System Improvement Program (WSIP). To address the potential environmental impacts of the proposed WSIP projects at a programmatic level, the San Francisco Planning Department prepared a Program Environmental Impact Report (PEIR) that was certified on October 30, 2008 (Motion No. 17734). The project mitigation measures listed below are based in part on the applicable WSIP PEIR mitigation measures. In some cases, they have been modified based on project-level detail and analysis. Refer to Appendix D for more detailed discussion of the WSIP PEIR program-level mitigation measures as they relate to the proposed project.

CEQA Section 15126.4 states that an EIR shall distinguish between mitigation measures which are proposed by the SFPUC to be included in the project and the measures that are proposed by the lead agency. At this time, the SFPUC intends to incorporate all mitigation measures presented in this EIR into the project and, therefore, all measures are considered to be proposed by the SFPUC. If any mitigation measures are not adopted by the SFPUC, the SFPUC would adopt a finding of overriding consideration before implementing actions that could result in significant impacts.

5.2 Mitigation Measures

This section presents all mitigation measures to address impacts described in Chapter 4. Mitigation measures for impacts identified in Sections 4.2 through 4.14 are presented under the respective environmental resource topic. Mitigation measures for cumulative impacts (Section 4.15) are also presented. All mitigation measures are numbered to correspond to the same impact numbers, although in some cases, the same measure would mitigate more than one impact. The numbering corresponds to the first impact identified and is cross-referenced so that measures are not duplicated. Table 1.1 in Chapter 1 summarizes project impacts and mitigation measures. Table 5-1 summarizes mitigation measures and identifies whether each measure applies to the Tesla Treatment Facility and/or the Lawrence Livermore Water Quality Improvements. A full description of each measure follows the table.

TABLE 5-1
SUMMARY OF APPLICABLE MITIGATION MEASURES BY PROJECT SITE

Mitigation Measures (summarized here – refer to complete text in section below)	Tesla Treatment Facility (Tesla Portal Site)	Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)

Mitigation Measure 4.15-1c – Coordination with Other Agencies	x	x

5.2.1 Land Use and Visual Quality

Architectural Design

Mitigation Measure 4.3-5a: The design of the proposed buildings at the Tesla Treatment Facility shall consider the existing visual character of the site and surrounding area, including the visibility of facilities and related structures from I-580. Proposed buildings shall be designed to minimize the intrusion of structures into the natural setting of the site by using colors that are compatible with the existing architecture and visual character of the site.

Landscape Screens (Trees or Berms)

Mitigation Measure 4.3-5b: In addition to revegetation of disturbed areas per SFPUC Standard Construction Measure #10 and Mitigation Measure 4.6-2, new plantings and/or a landscape berm shall be required to screen views of new structures and equipment from I-580 (a designated state scenic highway) to the extent possible, provided that such landscaping does not affect security of SFPUC facilities.

5.2.2 Geology, Soils and Seismicity

Characterize Extent of Expansive and Corrosive Soil

Mitigation Measure 4.4-9: If the screening analysis conducted in accordance with SFPUC Standard Construction Measure #2 identifies a potential for expansive or corrosive soils, the site-specific geotechnical investigation shall include a characterization of the presence and extent of expansive and corrosive soil at the project sites. The results and recommendations of the investigation shall be incorporated into the final project design for the Tesla Treatment Facility. For the Lawrence Livermore Water Quality Improvements, prior to construction, the SFPUC shall obtain soil samples for testing of corrosive/expansive soils and use to adjust the final project design of the pipeline, or, alternatively, the SFPUC shall implement a conservative design approach of the pipeline that shall address potential corrosivity.

5.2.3 Biological Resources

The proposed project would participate in the San Joaquin County Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) to mitigate impacts to aquatic habitat, natural lands and to obtain any necessary incidental take coverage for federally- and state- listed species. The SJMSCP is designed to provide a regional approach to mitigating development impacts on the 97 listed and non-listed plant, fish, and wildlife species covered by the SJMSCP and to compensate for the conversion of open space to non–open space uses. The SJMSCP provides incidental take authorization for covered projects that implement certain approved incidental take mitigation measures (ITMMs) and, if applicable, provides compensation for habitat losses through the collection of fees that are used to preserve habitats elsewhere.

Participate in the SJMSCP

- Mitigation Measure 4.6-1a: Prior to the commencement of construction activities, SFPUC shall coordinate with the Joint Powers Authority (JPA)/Technical Advisory Committee (TAC),

implement relevant ITMMs for applicable species (as identified in Mitigation Measures 4.6-3b through 4.6-3l, below) and pay any necessary fees to fund offsite compensation under the terms of the SJMSCP to provide replacement values that are equal to that of the permanent loss of 3.2 acres of California annual grasslands and 0.01 acre of ruderal/disturbed land, and temporary impacts to 11.72 acres of California annual grassland and 0.96 acre of ruderal/disturbed land, and incidental take authorization for special-status species.

Implement Best Management Practices

Mitigation Measure 4.6-1b: SFPUC shall implement Best Management Practices to ensure that natural flow is maintained in the ephemeral drainage during and after construction of the pipeline at the ephemeral drainage. Natural flow will be maintained by restricting construction to the dry season (e.g., April 15 – October 15) or by diverting water around the construction area (e.g., a dam and a pump) or through the construction area (e.g., a culvert) in the ephemeral drainage during the wet season (e.g., October 16 – April 14). The drainage channel will be restored and recontoured to pre-existing conditions after construction.

In addition, prior to the start of staging, ground disturbing activities, or large-scale materials off-haul or delivery, SFPUC shall require the contractor to implement the following actions intended to avoid or reduce indirect and direct impacts on the ephemeral drainage at the Tesla Portal site.

- SFPUC or its contractor(s) shall install appropriate erosion control (e.g., certified weed free straw bales, silt fencing, straw wattles, erosion and sediment control fabric) at the pipeline crossing and the intersections of the road and the ephemeral drainage to minimize potential for increased sedimentation and turbidity.

- SFPUC shall prohibit its contractor(s) from refueling, washing, and repairing equipment in and near (i.e., within at least 25 feet) the ephemeral drainage at the Tesla Portal project site.

- SFPUC shall require fencing of the ephemeral drainage (e.g., temporary construction "orange mesh" fencing or silt fencing) adjacent to the footprint of the pipeline crossing and the access road crossing, and shall require signage to be placed at the sites indicating that it is a restricted area. SFPUC shall require its contractor(s) to stay out of the fenced and signed area. SFPUC shall require its contractor(s) to limit vehicle speeds to 15 mph on unpaved roads in the vicinity of the fenced area ephemeral drainage to prevent dust effects. SFPUC shall also require its contractor(s) to control dust (i.e., stabilization of dust emissions using water or chemical stabilizer/suppressant) along the existing access road leading to the Tesla Portal project site, as required to control dust (refer also to Mitigation Measure 4.9-1a, SJVAPCD Dust Control Measures).

Return Site to Pre-Project Condition

Mitigation Measure 4.6-2: Vegetation removal and soil disturbance shall be limited to the minimum amount necessary for project implementation, especially where the existing access road comes near the artificial wetland, and where the proposed pipeline would cross both the artificial wetland and the ephemeral drainage. Where soils are disturbed and/or vegetation removed on the project site, such as in the construction staging area, the site shall be returned to pre-project

conditions (i.e., return site contours to pre-project profiles, restore original grades where possible, lightly compact loose soils or aerate compacted soils) where necessary. Where grading occurs, 12 inches of topsoil shall be salvaged and respread in graded areas as appropriate. When natural vegetation is disturbed, small areas (e.g., less than 100 square feet in size) shall be allowed to re-vegetate passively, while larger disturbed areas (e.g., more than 100 square feet in size or in areas prone to erosion such as sloped areas) shall be re-seeded with locally available native grasses and forbs (as needed).

Worker Awareness Program

Mitigation Measure 4.6-3a: Prior to the commencement of construction activities, a qualified biologist shall conduct a worker awareness program (environmental education) to inform project workers of the sensitive habitat and species potentially found onsite and their responsibilities with regards to protecting those sensitive biological resources.

Conduct Pre-Construction Surveys for San Joaquin Whipsnake and California Horned Lizard

Mitigation 4.6-3b: Prior to the start of construction, a qualified biologist shall conduct San Joaquin whipsnake surveys, and surveys for California horned lizard. These species are of very limited distribution within San Joaquin County, primarily isolated locations outside of anticipated development areas. Therefore, if discovered on a project site and prior to ground disturbance, ITMMs shall be formulated by the SJMSCP TAC and approved by the San Joaquin Council of Governments (SJCOG) with the concurrence of the Permitting Agencies' representatives on the TAC. ITMMs may consist of preconstruction surveys, avoidance techniques and/or buffer areas.

Implement Incidental Take Minimization Measures for San Joaquin Kit Fox

Mitigation Measure 4.6-3c: SFPUC shall implement the ITMMs identified for the San Joaquin kit fox under the SJMSCP to reduce the level of impact on the San Joaquin kit fox. Mitigation measures defined by the SJMSCP and the USFWS to protect the San Joaquin kit fox include the following:

- A qualified biologist with demonstrated experience in kit fox biology, identification, and survey techniques shall conduct preconstruction surveys two calendar weeks to 30 calendar days prior to commencement of ground disturbance. Surveys shall be conducted by qualified biologists. When surveys identify potential dens (potential dens are defined as burrows at least four inches in diameter which open up within two feet), potential den entrances shall be dusted for three calendar days to register track of any San Joaquin kit fox present. If no San Joaquin kit fox activity is identified, potential dens may be destroyed.
- If San Joaquin kit fox activity is identified, then dens shall be monitored to determine if occupation is by an adult fox only or is a natal den (natal dens usually have multiple openings). If the den is occupied by an adult only, the den may be destroyed when the adult fox has moved or is temporarily absent. If the den is a natal den, a buffer zone of 250 feet shall be maintained around the den until the biologist determines that the den has been vacated.

- Where San Joaquin kit fox are identified, the provisions of the U.S. Fish and Wildlife Service's published "Standardized Recommendations for Protection of the San Joaquin kit fox Prior to or During Ground Disturbance" shall apply (except that preconstruction survey protocols shall remain as established in this paragraph). These standards include provisions for educating construction workers regarding the kit fox, keeping heavy equipment operating at safe speeds, checking construction pipes for kit fox occupation during construction and similar low or no-cost activities.

Conduct Pre-Construction Surveys to Determine Presence/Absence of San Joaquin Pocket Mouse

Mitigation Measure 4.6-3d: Prior to the start of construction activities, a qualified biologist shall conduct surveys to determine the presence or absence of San Joaquin pocket mouse. If the species is not found, then no other mitigation is required. If the species is found in or near potential work areas, the SFPUC will coordinate with the SJMSCP TAC to formulate avoidance measures, such as buffer areas and limiting the time and extent of construction activities.

Conduct Pre-Construction Surveys for Burrowing Owls

Mitigation Measure 4.6-3e: Breeding Season Surveys.

- Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below: If project schedule permits, a qualified biologist will survey for burrows and burrowing owls during the breeding season (February 1 to August 31), immediately preceding construction. Surveys will be conducted within 500 feet of the project boundary (access permitting) in accordance with the California Burrowing Owl Consortium (1993) guidelines or as otherwise determined by CDFG. Burrows would be inspected for signs of owl activity (tracks, pellets, feathers, etc.). The locations of burrowing owl sightings, occupied burrows, and burrows with signs of owl activity will be marked on a map of the project area at a scale sufficient to accurately show the distance of active burrows to the limits of construction. Surveys will be conducted on at least four separate dates during the breeding season in areas where suitable burrows are present. If possible, surveys will be conducted during the peak of the burrowing owl breeding season, generally between April 15 and July 15.

- If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with CDFG, as to whether work will affect the occupied burrows or disrupt reproductive behavior.

- If it is determined that construction will not affect occupied burrows or disrupt breeding behavior, construction will proceed without any restrictions or mitigation measures.

Mitigation Measure 4.6-3f: Winter Surveys. Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below:

- If birds are not observed during breeding season surveys, or if breeding season surveys are infeasible due to project scheduling, or if construction will occur during the wintering season,

a winter survey will be conducted to identify non-breeding residents of the project site. Winter surveys will be conducted within 500 feet of the project site (access permitting) or as otherwise determined by CDFG during the period when wintering owls are most likely to be present (December 1 to January 31). The locations of burrowing owl sightings, occupied burrows, and burrows with signs of owl activity will be marked on a map of the project area at a scale sufficient to accurately show the distance of active burrows to the limits of construction.

- If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with CDFG, as to whether or not work will affect the occupied burrows.

- If it is determined that construction will not affect occupied burrows, construction will proceed without any restrictions or mitigation measures.

- If it is determined that construction will affect occupied burrows, the subject owls will be passively relocated from the occupied burrow(s) using one-way doors prior to the onset of breeding season. Owls will be encouraged to relocate to alternate burrows that are at least 160 feet from the construction limits. One alternate natural or artificial burrow for each burrow excavated will be in place at least one week before one-way doors are installed on occupied burrows. One-way doors will be in place for a minimum of 48 hours before burrows are excavated.

Mitigation Measure 4.6-3g: Fall Surveys. Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below:

- If surveys must be conducted between September 1 and November 30 (which is outside of the time windows specified above), a qualified biologist will conduct a survey for burrows and burrowing owls no more than thirty (30) days prior to ground-disturbing activity. If necessary, resident owls will be passively relocated from occupied burrows, as described above. If construction activities are still ongoing beyond November 30, then winter surveys will be conducted during December and January.

Conduct Pre-Construction Surveys for Swainson's Hawk

Mitigation Measure 4.6-3h: A qualified biologist shall conduct a preconstruction survey for Swainson's hawk, prior to the commencement of any ground disturbing construction activities (e.g., grass/vegetation/brush/tree removal, soil excavation, grading, vehicle access, staging of materials or vehicles, large scale materials off-haul or delivery, construction of temporary or permanent access roads).

In the case that Swainson's hawks are found nesting in the area, the SFPUC will notify CDFG. At a minimum, the following mitigations regarding Swainson's hawk, as listed from the SJMSCP, will be implemented:

- If a nest tree becomes occupied during construction activities, then all construction activities shall remain a distance of two times the dripline of the tree, measured from the nest.

- If any nest trees need to be removed, they may be removed between September 1 and February 15, when the nests are unoccupied.

- The following two measures will also be implemented:

  - If any unoccupied nests are found during preconstruction surveys, these nests may be removed when the nests are unoccupied.

- - If any occupied nests are found during preconstruction surveys, then all construction activities shall remain at a distance of ¼ mile (1,320 feet), unless CDFG agrees to other equally effective measures (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc).

Implement Incidental Take Minimization Measures for White-Tailed Kite

Mitigation Measure 4.6-3i: SFPUC shall implement the ITMM identified for the white-tailed kite under the SJMSCP, which consists of the following:

- A qualified biologist shall conduct preconstruction surveys and investigate all potential nesting trees on the project site (e.g., especially tree tops 15-59 feet above the ground in oak, willow, eucalyptus, cottonwood, or other deciduous trees), during the nesting season (February 15 to September 15) whenever white-tailed kites are noted on site or within the vicinity of the project site during the nesting season.

- - If the species is found nesting, a setback of 100 feet from nesting areas shall be established and maintained during the nesting season for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective measures (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc.) and CDFG shall be notified of the proposed buffer zone. This setback applies whenever construction or other

ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.

Implement Incidental Take Minimization Measures for California Horned Lark and Northern Harrier

Mitigation Measure 4.6-3j: SFPUC shall implement the ITMM identified for the California horned lark and northern harrier under the SJMSCP, which consists of the following:

- A qualified biologist shall conduct a preconstruction survey and investigate all potential nesting trees to determine the presence or absence of the species on the project site.

- If species are found, a setback of 500 feet from nesting areas shall be established and maintained during the nesting season (February 16 – August 31) for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc.), or offsite compensation shall be provided and CDFG shall be notified of the proposed buffer zone. If a setback is used, this setback would apply whenever construction or other ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.

Conduct Pre-Construction Surveys for Golden Eagle

Mitigation Measure 4.6-3k: Prior to the start of construction, a qualified biologist shall conduct golden eagle surveys as required by the SJMSCP. Additionally, SFPUC shall implement the ITMM identified for the golden eagle under the SJMSCP, which consists of the following:

- When a site inspection indicates the presence of a nesting golden eagle, CDFG will be notified and a setback of 500 feet from the nesting area shall be established and maintained during the nesting season (normally approximately February 1 – June 30) for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective measures (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc). This setback applies whenever construction or other ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.

Conduct Pre-Construction Surveys for Ferruginous Hawk and Prairie Falcon

- Mitigation 4.6-3l: Prior to the start of construction, a qualified biologist shall conduct surveys for ferruginous hawk and prairie falcon as required by the SJMSCP. These species currently do not nest in San Joaquin County and are not expected to nest in the County over the life of the SJMSCP. Therefore, in the highly unlikely event that one of these species is found nesting on a project site, SFPUC shall notify CDFG of the proposed buffer zone and setback of 500 feet from

the nesting area shall be established and maintained for the period encompassing nest building and continuing until fledglings leave the nests, unless CDFG agrees to other equally effective measures. ITMMs shall be formulated prior to ground disturbance by the TAC and approved by the JPA with the concurrence of the Permitting Agencies' representatives on the TAC in

accordance with the SJMSCP's Adaptive Management Plan. ITMMs may consist of preconstruction surveys, avoidance techniques, and buffer areas.

5.2.4 Cultural Resources

Paleontological Monitoring During Excavation

Mitigation Measure 4.7-1a: The SFPUC shall retain a qualified professional paleontologist to monitor excavations starting at the depth of 10 feet deep during construction at the Tesla Portal site for paleontological resources. Monitoring shall continue at the Tesla Portal site until the supervising qualified paleontologist determines that no native sediments are present or that significant paleontological resources are not likely to be discovered.

Suspend Construction Work if Paleontological Resource is Discovered

Mitigation Measure 4.7-1b: This mitigation measure builds on SFPUC Construction Measure #9 for cultural resources, which requires that construction work will be suspended immediately if there is any indication of a paleontological resource. When a paleontological resource (fossilized invertebrate, vertebrate, plant or micro-fossil) is discovered at any of the project sites, an appointed representative of the SFPUC will notify a qualified paleontologist, who will document the discovery as needed, evaluate the potential resource, and assess the significance of the find under the criteria set forth in Section 15064.5 of the CEQA Guidelines. When a fossil is found during construction, excavations within 50 feet of the find will be temporarily halted or diverted until the discovery is examined by a qualified paleontologist, in accordance with Society of Vertebrate Paleontology standards (Society of Vertebrate Paleontology, 1995). The paleontologist will notify the SFPUC to determine procedures to be followed before construction is allowed to resume at the location of the find. If the SFPUC determines that avoidance is not feasible, the paleontologist will prepare an excavation plan for mitigating the effects of the project.

Accidental Archaeological Discovery

Mitigation Measure 4.7-2a: SFPUC Standard Construction Measure #9 for cultural resources requires that construction activities be suspended immediately if there is any indication of an archaeological resource.

- To avoid any potential adverse effect from the proposed project on accidentally discovered buried or submerged historical resources as defined in CEQA Guidelines Section 15064.5(a)(c), the SFPUC shall distribute the Planning Department archaeological resource "ALERT" sheet to the project prime contractor; to any project subcontractor (including demolition, excavation, grading, foundation, pile driving, etc. firms); or utilities firm involved in soil disturbing activities within the project site. Prior to any soil disturbing activities being undertaken, each contractor is responsible for ensuring that the "ALERT" sheet is circulated to all field personnel including, machine operators, field crew, pile drivers, supervisory personnel, etc. The SFPUC shall provide the Environmental Review Officer (ERO) with a signed affidavit from the responsible parties

(prime contractor, subcontractor(s), and utilities firm) confirming that all field personnel have received copies of the "ALERT" sheet.

Should any indication of an archaeological resource be encountered during any soils disturbing activity of the project, the contractor and/or the SFPUC will immediately notify the ERO and will immediately suspend any soils disturbing activities within 100 feet of the discovery until the ERO has determined what additional measures should be undertaken.

- If the ERO determines that an archeological resource may be present within the project site, the SFPUC shall retain the services of a qualified archeological consultant. The archeological consultant shall advise the ERO as to whether the discovery is an archeological resource that retains sufficient integrity, and is of potential scientific/historical/cultural significance. If an archeological resource is present, the archeological consultant shall identify and evaluate the archeological resource. The archeological consultant shall make a recommendation as to what action, if any, is warranted. Based on this information, the ERO may require, if warranted, specific additional measures to be implemented by the SFPUC.

- Measures might include: preservation in situ of the archeological resource; an archaeological monitoring program; or an archeological evaluation program. If an archeological monitoring program or archeological evaluation program is required, it shall be consistent with the MEA WSIP Archaeological Guidance (San Francisco Planning Department, 2008) for such programs. The ERO may also require that the SFPUC immediately implement a site security program if the archeological resource is at risk from vandalism, looting, or other damaging actions.

- The project archeological consultant shall submit an accidental discovery Archaeological Data Recovery Report (ADRR) to the ERO, which, in addition to the usual contents of the ADRR, includes evaluation of the historical significance of any discovered archeological resource, as well as describing the archeological and historical research methods employed in the archeological monitoring/data recovery program(s) undertaken, and presenting, analyzing, and interpreting the recovered data. Information that may put at risk any archeological resource shall be provided in a separate removable insert within the final report.

- Once approved by the ERO, copies of the ADRR shall be distributed as follows: the relevant California Historical Resources Information System Information Center shall receive one (1) copy and the ERO shall receive a copy of the transmittal letter of the ADRR to the Information Center. The MEA shall receive three copies of the ADRR along with copies of any formal site recordation forms (CA DPR 523 series) and/or documentation for nomination to the National Register of Historic Places/California Register of Historical Resources. The SFPUC shall receive copies of the ADRR in the number requested. In instances of high public interest in or the high interpretive value of the resource, the ERO may require a different final report content, format, and distribution than that presented above.

Treatment of Human Remains

- Mitigation Measure 4.7-2b: The treatment of human remains and of associated or unassociated funerary objects discovered during any soils disturbing activity shall comply with applicable State

laws. This shall include immediate notification of the San Joaquin County Coroner and in the event of the coroner's determination that the human remains are Native American, notification of the California State Native American Heritage Commission (NAHC) who shall appoint a Most Likely Descendant (MLD) (Public Resources Code Section 5097.98). The

archaeological consultant, SFPUC, and MLD shall make all reasonable efforts to develop an agreement for the treatment of, with appropriate dignity, human remains and associated or unassociated funerary objects (CEQA Guidelines Section 15064.5(d)). The agreement should take into consideration the appropriate excavation, removal, recordation, analysis, custodianship, curation, and final disposition of the human remains and associated or unassociated funerary objects. California Public Resources Code allows 24 hours to reach agreement on these matters. If the MLD and the other parties do not agree on the reburial method, the project will follow Section 5097.98(b) of the California Public Resources Code which states, "the landowner or his or her authorized representative shall reinter the human remains and items associated with Native American burials with appropriate dignity on the property in a location not subject to further subsurface disturbance."

Architectural Resources Protection Plan

Mitigation Measure 4.7-3: The SFPUC shall retain a qualified historian to prepare a plan that specifies procedures for protecting historical resources at the Tesla Portal site during construction activities. The plan shall include a monitoring method to be employed by the construction contractor while working near these resources. At a minimum, the plan shall address the operation of construction equipment near or adjacent to the historical resource, storage of construction materials away from the resource, and education/training of construction workers about the significance of the historical resources. The plan shall also require the construction of a temporary protective barrier around the Southwest Valve House, such as construction fencing and/or vertical and horizontal netting to prevent physical damage to the valve house.

5.2.5 Air Quality

SJVAPCD Dust Control Measures

Mitigation Measure 4.9-1a: The following applicable general San Joaquin Valley Air Pollution Control District (SJVAPCD) recommended mitigation measures will be implemented to reduce emissions of fugitive PM_{10} dust from construction activities at both project sites, as specified in the Guide to Assessing and Mitigating Air Quality Impacts (GAMAQI), and in accordance with Regulation VIII Rules addressing construction (Rules 8011, 8021, 8031, 8041, 8051, 8061 and 8071).

SJVAPCD Regulation VIII Basic Control Measures:

- Adhere to the recordkeeping requirements specified in Rule 8011 (Section 6.2) for days that control measures are implemented

- Submit a Dust Control Plan (form available from SJVAPCD) in accordance with Rule 8021.

- All disturbed areas, including storage piles that are not being actively utilized for construction purposes, shall be effectively stabilized of dust emissions using water, chemical stabilizer/suppressant, covered with a tarp or other suitable cover, or vegetative ground cover in accordance with Rule 8031.

- All onsite unpaved roads and offsite unpaved access roads shall be effectively stabilized of dust emissions using water or chemical stabilizer/suppressant in accordance with Rule 8031.

- All land clearing, grubbing, scraping, excavation, land leveling, grading, cut and fill, and demolition activities shall be effectively controlled of fugitive dust emissions utilizing application of water or by presoaking in accordance with Rule 8021.

- Limit Visible Dust Emissions (VDE) to 20% opacity by applying water or chemical/organic stabilizers/suppressants or construct and maintain wind barriers sufficient to limit VDE to 20% opacity. If utilizing wind barriers, water or chemical suppressants shall also be implemented.

- When materials are transported offsite, all material shall be covered, or effectively wetted to limit visible dust emissions, and at least 6 inches of freeboard space from the top of the container shall be maintained in accordance with Rule 8031.

- All operations shall limit or expeditiously remove the accumulation of mud or dirt from adjacent public streets at the end of each workday. The use of dry rotary brushes is expressly prohibited except where preceded or accompanied by sufficient wetting to limit the visible dust emissions. Use of blower devices is expressly forbidden in accordance with Rule 8041.

- Following the addition of materials to, or the removal of materials from, the surface of outdoor storage piles, said piles shall be effectively stabilized of fugitive dust emissions utilizing sufficient water or chemical stabilizer/suppressant in accordance with Rule 8031.

- A trackout control device shall be installed and maintained at all access points to paved public roads or a carryout and trackout prevention procedure, which as been demonstrated to the satisfaction of the APCO and U.S. EPA, shall be implemented in accordance with Rule 8041.

- Trackout shall be immediately removed when it extends 50 or more feet from the nearest unpaved surface exit point of the site and at the end of each workday in accordance with Rule 8041.

SJVAPCD Enhanced Control Measures

- Traffic speeds on unpaved roads shall be limited to 15 mph and speed limit signs shall be posted in accordance with Rule 8021, Section 5.3.

SJVAPCD Exhaust Control Measures

Mitigation Measure 4.9-1b: The following mitigation measures will be implemented during construction of the proposed project to reduce exhaust emissions:

(1) SJVAPCD Guide to Assessing and Mitigating Air Quality Impacts Mitigation Measures:

To limit exhaust emissions within the San Joaquin Region, the SJVAPCD specifies the following exhaust controls for heavy-duty equipment (scrapers, graders, trenchers, earthmovers, etc.). The SFPUC will include these measures, where feasible and applicable, in contract specifications:

- Idling time (e.g., 5-minute maximum) shall be minimized.

- The hours of operation of heavy-duty equipment and/or the amount of equipment in use shall be limited.

- Activity management (e.g., rescheduling activities to reduce short-term impacts) shall be implemented.

(2) *Regulation IX – Mobile and Indirect Sources, Rule 9510 Mitigation Measures:*

Rule 9510 applies to any project subject to discretionary approval by a public agency that ultimately results in the construction of a new building, facility, or structure or reconstruction of a building, facility, or structure for the purpose of increasing capacity or activity and also involving 9,000 square feet of space. Rule 9510 requires exhaust emissions for construction equipment greater than 50 horsepower used or associated with a development project to be reduced by the following amounts from the statewide average as estimated by the California Air Resources Board (CARB):

- 20% of the total NO_X emissions
- 45% of the total PM_{10} exhaust emissions

An applicant may reduce construction emissions on-site by using less polluting construction equipment, which can be achieved by utilizing add-on controls, cleaner fuels, or newer lower emitting equipment. The requirements listed above can also be met through the payment of an off-site emissions reduction fee.

The following mitigation measures will be selectively applied to achieve compliance with the emission reductions set forth by Rule 9510:

- Selected construction equipment with engines equal to or greater than 50 horsepower will:
  - Be equipped with Tier 2 diesel engines as defined in Title 13, CCR, §2423

- Must be equipped with verified Level 3 (at least 85% reduction of PM from the baseline emission level) Diesel Emission Control Strategies as defined in Title 13, CCR, §2700 through 2710

- All construction vehicles will undergo monthly maintenance. Preventive maintenance includes complying with the manufacturer's service recommendations, using recommended types of fuel, maintaining proper fluid levels (such as oil, coolant, brake, and transmission), ensuring proper tire pressure, working signals, lights (including headlamps, turn-signal lights, tail lights, and brake lights), and brakes.

5.2.6 Noise and Vibration

Vacate SFPUC Caretaker's Residence at the Tesla Portal Site

Mitigation Measure 4.10-1: The SFPUC caretaker's residence at Tesla Portal shall be vacated during hours when construction activities at the site would produce daytime sound levels in excess of the speech interference criterion (an exterior noise level of 70 dBA) or nighttime sound levels in excess of the sleep interference criterion (an exterior noise level of 60 dBA).

Maintain Structural Integrity of San Joaquin Pipelines

Mitigation Measure 4.10-2: The construction contractor shall perform construction (cutting and connecting a new manifold) at the tie-in of the proposed UV Building to San Joaquin Pipelines 1 and 2 to maintain the structural integrity of the pipelines.

5.2.7 Energy Resources

Incorporation of Energy Efficiency Measures

Mitigation Measure 4.14-1: Consistent with the Energy Action Plan II priorities for reducing energy usage, the SFPUC shall ensure that energy efficient equipment is used in the proposed project at the Tesla Portal and the Thomas Shaft sites. A repair and maintenance plan shall also be prepared for each facility to minimize power use. Cooling, heating and ventilation rates will meet the standards of the American Society of Heating, Refrigeration and Air-Conditioning Engineers, California Building Code and the California Building Energy Efficiency Code. All ductwork will comply with Sheet Metal and Air Conditioning Contractors' National Association objectives. The SFPUC shall also include the use of renewable energy, such as solar power, at the Tesla Treatment Facility.

5.2.8 Cumulative Effects – Traffic

SFPUC WSIP Projects Construction Coordinator

Mitigation Measure 4.15-1a: Due to the potential for overlapping project activities in the SFPUC Western San Joaquin Region near the project sites, and the potential for construction vehicles to affect travel within and across different WSIP regions, the SFPUC shall identify a qualified construction coordinator responsible for coordinating project-specific traffic control plans, and for developing a public information campaign (e.g., internet website, radio and newspaper updates) to inform the public of construction activities, detour routes, and alternate routes.

Throughout the seven-year construction schedule for the San Joaquin WSIP projects, the SFPUC construction coordinator shall work with local and regional agencies to pursue additional traffic mitigation measures to minimize local and regional traffic impacts and will incorporate these measures into the project-specific traffic control plans, as appropriate.

Combined San Joaquin Regional Traffic Control Plan

Mitigation Measure 4.15-1b: Due to the potential for overlapping project schedules in the San Joaquin Region near the project sites, the SFPUC will develop, or the SFPUC's construction contractor(s) shall be required to develop, a San Joaquin Regional Traffic Control Plan. This plan will coordinate the project-specific traffic control plans that shall be developed for individual WSIP projects in the San Joaquin Region, and identify additional measures, if necessary, to minimize the combined impacts of multiple WSIP project construction traffic on I-580, Chrisman Road, and West Vernalis Road. As applicable, these measures shall be developed consistent with the standards of San Joaquin County, Stanislaus County, and Caltrans and could include:

- Additional traffic control devices, such as traffic signals at key intersections providing access to local roadways and land uses
- Additional traffic control personnel at key locations to facilitate vehicular traffic flow during peak periods of truck activity
- Adjustments in truck arrival and departure schedules for the various facilities (e.g., staggering departures)

Coordination with Other Agencies

Mitigation Measure 4.15-1c: The SFPUC WSIP construction coordinator shall coordinate with Caltrans, other county agencies, and local jurisdictions responsible for reviewing and/or approving the construction of other identified private and public development projects. Coordination efforts will be focused on minimizing traffic impacts on local access roads, particularly local streets where sensitive receptors (e.g., schools, residences, or hospitals) are located.

CHAPTER 6
Growth-Inducement Potential and Indirect Effects of Growth

6.1 Introduction and Overview

This chapter, as supplemented by Appendix B.2, analyzes the growth inducement potential and associated secondary effects of growth impacts of the proposed project, as required by the California Environmental Quality Act (CEQA). CEQA requires that an environmental impact report (EIR) evaluate the growth-inducing impacts of a proposed project.[1] A growth-inducing impact is defined as follows:

> [T]he ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth…. It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment.

- The PEIR on the San Francisco Public Utilities Commission's (SFPUC's) Water System Improvement Program (WSIP) concluded that the WSIP as a whole would support growth in the existing SFPUC service area. And, as explained in Chapter 3, Project Description, the proposed project is a component of the WSIP and thus contributes to its indirect growth inducement effect. By providing additional water supply to SFPUC customers within the SFPUC service area, the WSIP, and the proposed project, as part of the WSIP, would have an indirect growth-inducing effect according to the CEQA definition above.[2]

- Implementation of the WSIP would meet customer purchase requests through the year 2018, as discussed in the PEIR. Meeting additional purchase requests would provide water to serve additional residential and business customers in the existing SFPUC service area.

- The proposed project would not directly induce population or economic growth, nor would it tax existing community service facilities or encourage other activities that could significantly affect the environment. However, the proposed project is one of several improvement projects that comprise the WSIP, and implementation of the WSIP would support growth in the SFPUC service area, thereby contributing indirectly, to environmental impacts caused by that growth (see

[1] CEQA Guidelines Section 15126.2(d).

[2] The WSIP would not *directly* induce growth as it does not involve the development of new housing to attract additional population, nor would it indirectly induce growth by establishing substantial permanent or even short-term construction employment opportunities that could stimulate population growth. Construction of the WSIP projects is not expected to involve employment opportunities substantially beyond what would normally be available to construction workers in the area, and workers are expected to be drawn from the local labor pool.

below, Indirect Effects of Growth). The SFPUC service area spans seven counties—Tuolumne, Stanislaus, San Joaquin, Alameda, Santa Clara, San Mateo, and San Francisco.

- The project is primarily proposed to ensure that the SFPUC maintains high-quality water that meets or exceeds regulatory standards for drinking water into the future and, therefore, would contribute to the WSIP's water quality goal. The proposed project would also contribute to the WSIP's seismic reliability goal by reducing the system's vulnerability to earthquakes through the construction of a new chlorination facility at the Tesla Portal site designed to meet current seismic standards, and designed to treat additional water supply up to 313 million gallons per day consistent with the WSIP. Because the proposed project is part of the WSIP, the project would also contribute indirectly to the WSIP's growth inducement impact.

  A variety of factors influence new development or population growth in the area served by SFPUC water, including economic conditions of the region, adopted growth management policies in the affected communities, and the availability of adequate infrastructure (e.g., water service, sewer service, public schools, and roadways, etc.), with economic factors generally the lead driver. While water service is only one of many factors affecting the growth potential of a community, it is one of the chief public services needed to support urban development, and lack of a reliable water supply as well as a service capacity deficiency could constrain future development.

  Pursuant to CEQA, growth *per se* is not assumed to be necessarily beneficial, detrimental, or of little significance to the environment; it is the secondary, or indirect, effects of growth that can cause adverse changes to the physical environment. The indirect effects of population and/or economic growth and accompanying development can include increased demand on community services and public service infrastructure; increased traffic and noise; degradation of air and water quality; and conversion of agricultural land and open space to urban uses. Local land use plans (e.g., general plans and specific plans) of the jurisdictions served by the SFPUC establish land use development patterns and growth policies that are intended to allow for the orderly expansion of urban development supported by adequate public services, including water supply, roadway infrastructure, sewer service, and solid waste service. Local jurisdictions conduct CEQA environmental review on their general and specific plans to assess the secondary effects of their planned growth. A project that would induce growth that is inconsistent with local land use plans and policies could indirectly cause adverse environmental impacts, as well as impacts on public services, that the local land use jurisdictions have not previously addressed in the CEQA review of their land use plans and development proposals.

- By removing the lack of a reliable water supply and water system (as one potential obstacle to growth within the SFPUC service area) and providing and assisting in development of additional water supply sources, such as recycled water and groundwater projects as well as promotion of more efficient use of water through conservation measures, the WSIP would have an indirect growth-inducing effect according to the CEQA definition above. The WSIP would support growth in the SFPUC service area through 2018, although it appears that some growth would occur irrespective of the WSIP due to increased water delivery efficiencies (e.g., plumbing code changes), conservation, and other water supply sources. Growth would in turn result in indirect effects. In

most cases, the effects of population and employment growth have been identified and addressed in the EIRs for the general plans and associated area plans and specific plans adopted by the jurisdictions in the service area. Some of the identified indirect effects of growth are potentially significant and unavoidable; others are significant but can be mitigated.

- Potentially significant and unavoidable impacts as a result of growth in the SFPUC service area could occur in the following areas: traffic congestion, air pollution, traffic noise, construction noise, increased demand for public schools and other public services, loss of recreational opportunities and impacts on visual quality resulting from the loss of open space, cumulative effects on over-utilized parks, loss of wildlife habitat and wetlands and impacts on other biological resources, cumulative impacts on cultural resources, increased flooding potential, increased urban runoff pollutants, seismic hazards, induced population growth, failure to meet housing demand for projected population growth, exposure of new development to contaminated soil or groundwater, insufficient water supply, insufficient wastewater disposal capacity, loss of agricultural resources, land use conflicts, conflicts with existing land use plans or policies, and changes in density, scale, and character of an area.

- The adopted WSIP would have growth-inducement potential through 2018 because the SFPUC (with the cooperation of the wholesale customers) would provide the additional water supply to meet purchase requests though 2018. The WSIP would support much of the growth through 2018 in the jurisdictions served by the SFPUC regional water system. In general, development that was planned and approved through the general plan process in the SFPUC service area would have environmental impacts. The environmental consequences of this planned growth have been largely addressed in local plans and the associated CEQA review as well as in other, project-specific documentation. In a number of jurisdictions, negative declarations or mitigated negative declarations were prepared for general plans and related planning documents that were found not to have significant environmental effects.

- With the exception of the No Purchase Request Alternative, all of the alternatives analyzed in the PEIR contribute in similar ways to growth inducement impacts, since each of the alternatives provides different ways of meeting future water supply demand as one of the WSIP objectives. It is also likely that the water customers would find alternate sources of water to meet future demand under the alternatives that are not effective in meeting demand like the Aggressive Conservation and Recycling Alternative. Under this scenario, the alternative itself may not be growth-inducing, but growth could still occur. No mitigation measures were proposed for implementation by the SFPUC that could substantially decrease or eliminate growth-inducing impacts because the SFPUC does not have control over the decisions that each local agency will make with respect to growth in their jurisdictions. Individual agencies' general plans and environmental documents contain actions, limitations and mitigation measures that will be implemented in the individual jurisdictions with local development project or program approvals. These types of mitigation measures were identified in the PEIR (see Appendix B of this EIR.)

- To assess the growth inducement potential of the WSIP and characterize the secondary effects of growth, the PEIR investigated the following questions:

- *What assumptions did the SFPUC and its wholesale customers make regarding growth (population and employment) in projecting future (2030) total water demand and customer purchases from the SFPUC?*

- *Are these assumptions consistent with forecasts prepared and used by local and regional planning agencies (e.g., ABAG, counties and cities) within the service area? What are the growth trends in the Bay Area region?*

- *Are there any notable inconsistencies between the population and employment forecasts used by the SFPUC and the wholesale customers and those of the local and regional planning agencies that suggest that the water supply planning efforts are inconsistent with land use planning efforts?*

- *Is the level of growth projected for 2030 consistent with that identified and planned for in existing adopted general plans?*

- *What are the potential environmental impacts (secondary effects) associated with growth projected to occur in the service area? Have these impacts been evaluated in previous CEQA review documents on existing general and specific plans?*

- *What mitigation measures and findings have the local jurisdictions adopted as part of approving their future growth plans?*

The issues raised in these questions are summarized below and addressed in detail in Appendix B.2.

- *SFPUC Projections (Section 7.2 in Appendix B.2)*. Accurate demand projections are important in ensuring that future water supplies will be adequate while not surpassing the needs of planned growth. SFPUC and its customers used computer models to forecast future water demand. Section 7.2 presents an overview of the SFPUC water service area, and describes key factors (assumptions, inputs, and methodologies) used in estimating future demand that relate to growth and inform comparisons between water demand and land use planning projections. These factors include baseline population, methodology used to determine existing water usage by land use/account type, the current water supply agreement between the SFPUC and its wholesale customers, and assumptions regarding future land use patterns, water conservation and recycling, and water from other (non-SFPUC) sources through 2030. The demand estimates, in conjunction with estimates of savings from conservation and use of other water sources, provide the basis for the 2030 purchase estimates.

- *Growth Inducement Potential (Section 7.3 in Appendix B.2)*. This section analyzes the WSIP's growth inducement potential: whether the demand to be met by the WSIP would be consistent with local plans and policies or could contribute to growth in the service area beyond that called for in the existing general plan. To gauge the consistency of the WSIP with growth planned in the jurisdictions served by the SFPUC, the analysis compares the growth assumed in the SFPUC projections with growth forecasts (a) developed by ABAG and (b) reflected in adopted land use plans in the service area. With respect to ABAG, this section also describes ABAG's changing expectations about growth as reflected in its updated projections issued in 2002, 2003 and 2005.

- *Indirect Effects of Growth (Section 7.4 in Appendix B.2)*. Growth (whether planned or unplanned) can cause environmental impacts. Section 7.4 describes the potential impacts of growth that could be supported, in part, by implementation of the WSIP. This section also identifies measures adopted to reduce, eliminate or otherwise mitigate the impacts of planned growth.

6.2 Summary of Conclusions

- A review of historical growth trends of a selection of jurisdictions in the service area, based primarily on information in general plans and Bay Area Water Supply and Conservation Association profiles, shows that:

  - Cities in the service area are largely urbanized, most having experienced their most rapid growth in the postwar decades through the 1970s.

  - Milpitas and East Palo Alto have experienced high rates of growth more recently.

  - San Francisco's population fluctuated somewhat but on average has been essentially stable over the past 50 years.

  - Many jurisdictions cannot grow laterally and their general plans include policies to manage growth; many general plans identify strategies consistent with "smart growth" principles, such as encouraging infill development and the redevelopment of previously developed areas, as means to accommodate future growth.

  - The SFPUC's wholesale customers vary widely, in a variety of ways: by size, overall demand projected for 2030, the change that the 2030 demand represents in absolute terms and as a percentage of 2001 demand, and the degree to which the customers depend on the SFPUC for their water supply. As such, the WSIP would remove growth obstacles to varying degrees within the service area.

- As stated above, the complete growth inducement analysis is included in this EIR as Appendix B.2.

6.2.1 Indirect Effects of Growth

The indirect effects of growth expected in the general plans of jurisdictions in the service area have been identified in the EIRs prepared for those plans. A table of impacts commonly identified as significant and unavoidable and those commonly identified as significant but mitigable is presented in Section 7.4 in Appendix B.2.

- The most commonly identified significant and unavoidable impacts of growth are:

  – Increased traffic congestion

  – Deterioration of air quality

  - Cumulative effects of increased air pollutant emissions and noise

- Mitigation measures have been adopted by local jurisdictions as part of their general plan approval processes to address the secondary effects of planned growth. These measures are summarized in Appendix B.2.

- Two cities identified increased demand for potable water supply as a significant and unavoidable effect of growth; the WSIP would address this issue in those two cities by providing for increased supply and related water treatment facility and storage upgrades to reliably meet projected demand.

- Overriding considerations commonly adopted by the decision-making bodies in adopting their general plans include the following:

  - Accommodation of growth in an orderly, fiscally sound manner

  - Economic diversification and job generation

  - Creation of housing, furtherance of regional housing share objectives, and provision of affordable housing

  - Improvements of the local jobs/housing balance

  - Increased sales revenue and positive fiscal impact

  - Promotion of alternative modes of travel to reduce reliance on private vehicles

  - Establishment of policies to preserve natural areas and open space lands

- For many cities that receive water from the SFPUC regional system, the supply to be provided under the WSIP supports and is consistent with the planned growth reflected in their existing adopted general plans. For other communities, it appears that the WSIP supply (in combination with other supply sources available to those communities), could serve a level of growth beyond that identified in the existing general plans. In those cases, secondary effects of such growth could include impacts related to increased density and impacts related to development of new land areas.

  - Density related impacts could include, e.g., increased traffic congestion, air pollution, traffic noise, construction noise, and demand on public services.

  - Land area related impacts could include, e.g., loss of open space and agricultural land, loss of and degradation of water quality due to increases in impervious surface area.

- See Appendix B.2 in this EIR for additional detail on the proposed project's growth inducement effects.

CHAPTER 7

Significant Environmental Effects That Cannot Be Avoided if the Proposed Project Is Implemented

In accordance with Section 21067 of the California Environmental Quality Act (CEQA) and with Sections 15126(b) and 15126.2(b) of the CEQA Guidelines, the purpose of this section is to identify environmental impacts that cannot be eliminated or reduced to a level of less than significant by mitigation measures. Chapter 4, Environmental Setting and Impacts, and Chapter 5, Mitigation Measures, describe the potential environmental impacts of the proposed project and recommend feasible mitigation measures to reduce those impacts. The recommended mitigation measures would reduce potentially significant project-specific impacts identified in Chapter 4 to less-than-significant levels.

- However, as discussed in this EIR, the proposed project is one of several improvement projects that comprise the San Francisco Public Utilities Commission (SFPUC) Water System Improvement Program (WSIP).Insofar as the proposed project is a component of the WSIP, it would contribute to the WSIP's unavoidable water supply and growth-inducement impacts, as follows:

- **Potentially Significant and Unavoidable WSIP Water Supply Impacts**

- • Fisheries (Upper and Lower Crystal Springs Reservoir): Effects in the Peninsula watershed on fishery resources in Crystal Springs Reservoir in San Mateo County; and

- • Growth Inducement: Indirect growth-inducement impacts in the SFPUC service area.

- **Significant and Unavoidable WSIP Water Supply Impacts**

- • Streamflow (Alameda Creek below Alameda Creek Diversion Dam): Effects on stream flow in Alameda Creek between the diversion dam and the confluence with Calaveras Creek.

CHAPTER 8
Significant Irreversible Environmental Changes

In accordance with Section 21100(b)(2)(B) of CEQA and with Sections 15126(c) and 15126.2(c) of the CEQA Guidelines, the purpose of this section is to identify significant irreversible environmental changes that would be caused by the proposed project. Construction and operational impacts associated with improvements proposed at the Tesla Portal and Thomas Shaft sites would result in an irretrievable and irreversible commitment of natural resources through the use of power supply, and construction materials.

Improvements proposed at both the Tesla Portal and Thomas Shaft sites would require the commitment of energy resources to fuel and maintain construction equipment (such as gasoline, diesel, and oil) during the construction process. Construction of the Tesla Treatment Facility project would commit resources, such as concrete and steel, to be used for the proposed Chemical Process Building, Office/Control Building, and UV Building as well as new piping and other related site improvements. However, concrete and steel from projects constructed above ground can generally be reused or recovered. The Tesla Treatment Facility would also commit asphalt materials for the construction of roadway and parking lot improvements.

Operational impacts at the Tesla Treatment Facility would increase demand for energy use resulting from the installation of 12 ultraviolet reactors to be used for water treatment. Overall, the SFPUC would have the ability to provide for the increased energy demand anticipated for the project. However, SFPUC may need to supplement its energy supply during the summer and fall months[1] with PG&E power, which is generated in large part by fossil fuel based sources.

Construction and operation of the Lawrence Livermore Water Quality Improvements at the Thomas Shaft site would not require a significant commitment of resources given the relatively small scope of the project.

[1] SFPUC energy production varies by season and year depending on hydrologic conditions. During summer and fall months SPFUC often supplements its power supply with PG&E produced power in order to allow water to be stored while continuing to meet its municipal demand and contractual obligations for power supply.

CHAPTER 9
CEQA Alternatives

9.1 Introduction

California Environmental Quality Act (CEQA) Guidelines Section 15126.6(a) requires environmental impact reports (EIRs) to describe and evaluate the comparative merits of a range of reasonable alternatives to projects, or to project locations, which would: (1) feasibly attain most of the basic project objectives; and (2) avoid or substantially lessen any of the projects' significant effects. An EIR need not consider every conceivable alternative. Rather, it must consider a reasonable range of potentially feasible alternatives that will foster informed decision-making and public participation. The CEQA Guidelines set forth the following criteria for selecting and evaluating alternatives:

- The discussion of alternatives shall focus on alternatives to the project or its location which are capable of avoiding or substantially lessening any significant effects of the project, even if these alternatives would impede to some degree the attainment of the project objectives, or would be more costly (Section 15126.6(b)).

- The range of potential alternatives shall include those that could feasibly accomplish most of the basic objectives of the project and could avoid or substantially lessen one or more of the significant effects (Section 15126.6(c)).

- The EIR should also identify any alternatives that were considered by the lead agency but were rejected as infeasible during the scoping process and briefly explain the reasons underlying the lead agency's determination, e.g., (i) failure to meet most of the basic project objectives, (ii) infeasibility, or (iii) inability to avoid significant environmental impacts (Section 15126.6(c)).

- The specific alternative of "no project" shall also be evaluated along with its impact (Section 15126.6(e)(1)).

- If the environmentally superior alternative is the "no project" alternative, the EIR shall also identify an environmentally superior alternative among the other alternatives (Section 15126.6(e)(2)).

- The alternatives shall be limited to ones that would avoid or substantially lessen any of the significant effects of the project. Of those alternatives, the EIR need examine in detail only the ones that the lead agency determines could feasibly attain most of the basic objectives of the project (Section 15126.6(f)).

- The proposed project is a component of the San Francisco Public Utilities Commission's (SFPUC) Water System Improvement Program (WSIP). As required by CEQA, the Program EIR (PEIR) evaluated a range of alternatives to the WSIP. This proposed project, which is listed as three separate projects in the PEIR: the Tesla Portal Disinfection Facility, the Hetch Hetchy Advanced Disinfection, and the Lawrence Livermore Supply Improvements, is included in all of the WSIP alternatives. The PEIR No Program Alternative includes the Hetch Hetchy Advanced Disinfection as it is an improvement to comply with the new federal drinking water regulatory requirements contained in the Long Term 2 Enhanced Surface Water Treatment Rule. The remainder of the proposed project evaluated in this EIR is not included in the PEIR No Program Alternative. The WSIP alternatives are summarized in Section 9.2 and are analyzed in detail in Chapter 9 of the PEIR, which is included in Appendix B.3 of this document.

9.2 WSIP Alternatives

- The PEIR evaluated seven alternatives to the WSIP, summarized below, because of their apparent ability to meet most of the WSIP's goals, their ability to reduce one or more of the potentially significant impacts associated with program implementation, their potential feasibility, and their collective ability to provide a reasonable range of alternatives to foster informed decision-making and public participation. Analysis of the No Program Alternative is included as required by CEQA. Appendix B.3 includes more detailed descriptions of these WSIP alternatives, and also presents the associated program-level environmental analysis.

- The WSIP that was ultimately adopted by the SFPUC incorporates elements of three alternatives to the originally proposed WSIP: the No Purchase Request Alternative, the Aggressive Conservation/Water Recycling and Groundwater Alternative, and the Modified WSIP Alternative.

9.2.1 No Program Alternative

Under the No Program Alternative, the SFPUC would implement only those facility improvement projects driven by regulatory requirements including the ultraviolet (UV) building proposed as part of the San Joaquin Regional Water Quality Improvement Project, or existing agreements with regulatory agencies thus meeting only the water quality goals of the WSIP. It would endeavor to meet increasing customer purchase requests through the year 2030 by diverting additional Tuolumne River water only when available under City and County of San Francisco's (CCSF) existing water rights. The wholesale customers would have to pursue supplemental supply sources and/or conservation measures to make up the supply shortfall/reduced reliability under this alternative. Compared to the WSIP, this alternative would develop less in terms of new water supplies for the regional system and would implement fewer of the proposed facility improvement projects.

9.2.2 No Purchase Request Increase Alternative

The No Purchase Request Increase Alternative is designed to serve wholesale customers only the amount of water required under the existing Master Water Sales Agreement between the CCSF and each of the wholesale customers; therefore, this alternative would not fully meet the purchase request increase by the SFPUC wholesale customers for an additional 35 million gallons per day (mgd) supply through 2030. This alternative is included in the alternatives analysis in an effort to avoid or minimize potential growth-inducing effects and secondary effects of growth associated with providing more water to the SFPUC's regional customers.

9.2.3 Aggressive Conservation/Water Recycling and Local Groundwater Alternative

- Under the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, the SFPUC would implement all of the WSIP facility improvement projects, but would endeavor to serve the projected increase in customer purchase requests through 2030 only through additional conservation, water recycling, and local groundwater projects. Under this Alternative the SFPUC would have to either: (a) limit future customer purchase deliveries to the level that can be met, short of 2030 requests (approximately 294 mgd instead of 300 mgd average annual) and increase the level of rationing to 25 percent or more during droughts, or (b) provide a supplemental supply to make up the delivery shortfall to meet the 300 mgd.

9.2.4 Lower Tuolumne River Diversion Alternative

- Under the Lower Tuolumne River Diversion Alternative, the SFPUC would implement all of the proposed facility improvement projects and would serve the projected increase in customer purchase requests through 2030 through diversions from the lower Tuolumne River near its confluence with the San Joaquin River, assuming an agreement can be reached with the Turlock Irrigation District and the Modesto Irrigation District. This alternative would include construction and operation of additional conveyance and treatment facilities to divert, transport, treat, and blend the new supply into the regional water system.

9.2.5 Year-round Desalination at Oceanside Alternative

Under the Year-round Desalination at Oceanside Alternative, the SFPUC would implement all of the proposed WSIP facility improvement projects and would construct a 25-mgd desalination plant in San Francisco to serve the projected increase in customer purchase requests through 2030. The desalination plant would provide year-round supplies during all hydrologic year types to blend into the regional system at the Sunset Reservoir in San Francisco. Compared to the WSIP, this alternative represents an alternative source of supply and is evaluated to address the impacts to the Tuolumne River, Alameda Creek, and Peninsula Watersheds, including Pilarcitos Creek, and related resources.

9.2.6 Regional Desalination for Drought Alternative

Under the Regional Desalination for Drought Alternative, the SFPUC would implement all of the proposed WSIP facility improvement and would partner with other Bay Area water agencies to construct and operate a regional desalination plant that would provide the SFPUC with supplemental supply during drought years.

9.2.7 Modified WSIP Alternative

- Under the Modified WSIP Alternative, the SFPUC would implement all of the proposed facility improvement projects, but would modify proposed system operations to minimize environmental effects. This alternative would include the implementation of key mitigation measures identified in the PEIR.

9.2.8 Comparison of Alternatives to the WSIP

The seven alternatives analyzed in the PEIR would have varying abilities to meet the goals and objectives established by the SFPUC for the WSIP and would have a wide range of additional environmental effects. The No Program, No Purchase Request Increase, and Aggressive Conservation/Water Recycling and Local Groundwater Alternatives would fail to meet one or more key program objectives, while the Lower Tuolumne River Diversion, Year-round Desalination at Oceanside, Regional Desalination for Drought, and Modified WSIP Alternatives would meet most of the basic program objectives. The SFPUC found that many of the Alternatives would have greater environmental impacts than the adopted WSIP. (See SFPUC Resolution No. 08-0200.)

9.3 Alternatives Analysis

This section describes and evaluates five project-specific alternatives to the proposed project (including two No Project Alternatives) selected for detailed analysis and comparison with the proposed project (see Table 9-1). The project objectives, as listed in Chapter 3, consist of:

- Tesla Treatment Facility (Tesla Portal Site)
  - Replace existing water treatment facilities that are not currently seismically safe with new facilities that are designed to meet current seismic, safety/fire, and building code standards
  - Construct new water treatment facilities to meet U.S. Environmental Protection Agency (U.S. EPA) requirements for *Cryptosporidium* reduction/inactivation in drinking water, as required under the U.S. EPA's Long Term-2 Enhanced Surface Water Treatment Rule (LT2ESWTR)
  - Improve current water quality management capabilities such as pH control
- Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)
  - Construct new water treatment facilities to meet U.S. EPA requirements under the Surface Water Treatment Rule (SWTR) for the reduction/inactivation of *Giardia*, as well as assist in meeting LT2ESWTR *Cryptosporidium* requirements to enable delivery of potable water to LLNL from the Thomas Shaft of the Coast Range Tunnel.

In addition to the five alternatives analyzed below, Section 9.4 presents 11 additional alternatives that were considered as alternatives to the proposed project, but were not carried forward for further consideration because they did not meet most of the project's basic objectives or because they would clearly result in significant environmental impacts beyond those of the proposed project.

The five alternatives were selected for detailed analysis because they: 1) would meet most or all of the project's basic objectives; and 2) would avoid or reduce significant impacts associated with the proposed project (refer to Table 9-2). The five alternatives are:

- Alternative 1: No Project Alternative (Status Quo)
- Alternative 2: No Project Alternative (Compliance with Safe Drinking Water Regulations)

- Alternative 3: Continue Water Source to Artificial Wetland at Tesla Portal Site
- Alternative 4: Combine Office/Control Building and UV Building at Tesla Portal Site
- Alternative 5: Retrofit of Existing Tesla Portal Hypochlorite Station Building

TABLE 9-1

SUMMARY OF COMPONENTS OF ALTERNATIVES

Project Components	Proposed Project	Alternative 1: No Project (Status Quo)	Alternative 2: No Project (Compliance with Safe Drinking Water Regulations)	Alternative 3: Continue Water Source to Wetland	Alternative 4: Combine Office and UV Buildings	Alternative 5: Retrofit of Existing Building
New Buildings (with area of ground disturbance in sf)	• Chemical Bldg (14,000 sf) • Office Bldg (3,500 sf) • UV Bldg (20,000 sf)	• None	• UV Bldg (20,000 sf)	• Chemical Bldg (14,000 sf) • Office Bldg (3,500 sf) • UV Bldg (20,000 sf)	• Chemical Bldg (14,000 sf) • UV/Office Bldg (20,000 sf)[1]	• Office Bldg (3,500 sf) • UV Bldg (20,000 sf)
Retrofit Facilities	None	None	None	None	None	Hypochlorite Station Building retrofitted
Temporary Facilities	None	None	None	None	None	Chemical feed facility (400 sf)
Year-round water source to wetland	No	Yes	Yes	Yes	No	No
Meets project objectives?	Yes	No	Partially	Yes	Yes	Partially

[1] This alternative would combine the office/control building with the UV building in a single two-story structure instead of two separate single-story structure as under the Proposed Project.

Note: Proposed project components at the Thomas Shaft Site are the same under all alternatives (except the No Project Alternative).

A detailed discussion of each of the selected project alternatives and a comparison of the significant impacts of the proposed project to the impacts of each alternative follows. In those cases where an alternative may result in additional significant impacts (relative to the proposed project), these impacts are also identified. A comparative summary of the impacts associated with the alternatives is presented in Table 9-3.

TABLE 9-2

SELECTED ALTERNATIVES FOR CEQA ANALYSIS

Alternative/Description	How does this Alternative differ from the project?	What project impact(s) is this Alternative intended to reduce?
Alternative 1: No Project Alternative (Status Quo) – The existing Tesla Portal and Thomas Shaft sites would remain in their current condition; the same amount of chemical deliveries would be made to the Tesla Portal site; the same number of employees would continue to work at the Tesla Portal site; runoff from sampling points at the existing Tesla Portal Hypochlorite Station would continue to feed the artificial wetland.	There would be no construction of new facilities, modification of existing facilities, new water discharges, trenching, or operational changes at either site. Additionally, there would be no roadway improvements, new lighting, or a new transformer at the Tesla Portal site. The current disinfection facility at the Tesla Portal site would be non-compliant with seismic, safety/fire, and building code standards; the SFPUC drinking water supply would not meet federal standards, resulting in monitoring, testing, or treatment violations; and the Thomas Shaft facility would not fulfill contractual requirements with LLNL.	Required by CEQA. However, this alternative is unrealistic, given that the SFPUC would violate state and federal safe drinking water regulations, and delivery to customers after the compliance date would be prohibited under this alternative.
Alternative 2: No Project Alternative (Compliance with Safe Drinking Water Regulations) – The 20,000-square-foot UV building would be constructed; no other aspects of the project would occur.	Only the 20,000-square-foot UV building would be constructed.	Required by CEQA, but unlike the No Project Alternative (Status Quo), this alternative would allow the SFPUC to comply with state and federal safe drinking water regulations and continue to provide customers with water supply.
Alternative 3: Continue Water Source to Artificial Wetland at Tesla Portal Site Alternative – New analyzer equipment would supply the artificial wetland at the Tesla Portal site with a year round source of water roughly proportionate to the current amount; all other aspects of the proposed project remain the same.	The water supply to the artificial wetland area at the Tesla Portal site would not be cut-off.	Permanent loss of 0.308 acre of artificial wetland habitat at the Tesla Portal site and associated loss of habitat value to dependent plant and wildlife species.
Alternative 4: Combine Office/Control Building and UV Building at Tesla Portal Site Alternative – The 3,500-square-foot Office/Control Building and the UV Building would be combined in a single, two-story structure; all other aspects of the proposed project remain the same.	The building footprint at the Tesla Portal site would be smaller.	Severity of biological and cultural resource impacts Severity of fugitive dust impacts Severity of erosion and sedimentation Reduction in land suitable for grazing purposes
Alternative 5: Retrofit of Existing Tesla Portal Hypochlorite Station Building Alternative – The existing building that contains the Tesla Portal Hypochlorite Station would be retrofitted and a new Chemical Process Building would not be constructed at the Tesla Portal site. All other aspects of the proposed project remain the same.	The building footprint at the Tesla Portal site would be smaller.	Severity of biological and cultural resource impacts Severity of fugitive dust impacts; Severity of erosion and sedimentation Reduction in land suitable for grazing purposes

9.3.1 Alternative 1: No Project Alternative (Status Quo)

Description

CEQA Guidelines Section 15126.6(e)(3)(B) describes the "No Project" Alternative as the circumstance under which the proposed project does not proceed. Consideration of the No Project Alternative is required under Section 15126(f) of the CEQA Guidelines. The purpose of describing and analyzing a No Project Alternative is to allow decision-makers to compare the impacts of approving the proposed project with the impacts of not approving the proposed project (CEQA Guidelines Section 15126.6(e)(1)). The existing conditions for the No Project Alternative are the same as those described in the Notice of Preparation for the proposed project (refer to Appendix A).

The No Project Alternative includes those activities that would reasonably be expected to occur in the foreseeable future if the proposed project were not approved. These activities include the following:

- Continued operation and maintenance of the Tesla Portal and Thomas Shaft facilities
- Continued deliveries of chemicals to the Tesla Portal and Thomas Shaft facilities
- Continued staffing of three full-time equivalent personnel at the Tesla Portal site
- Continued discharge to the artificial wetland

The No Project Alternative would not include seismic upgrades to minimize the vulnerability of the existing disinfection facilities at the Tesla Portal site from the threat of a seismic event. According to the Hetch Hetchy Water Treatment Project Tesla Portal Chlorination System Evaluation, prepared by the San Francisco Water Team in September 2001, "it is important to note that many elements of the existing facility are at least 60 years old (e.g., the building itself) and cannot perform to the same standards as new facilities when considered from high risk adverse situations, such as a major seismic event, fire, or malicious vandalism."

Furthermore, the No Project Alternative would not include improvements to inactivate *Cryptosporidium* and *Giardia* in drinking water to meet U.S. EPA requirements. Compliance with the U.S. EPA's Long Term-2 Enhanced Surface Water Treatment Rule (LT2ESWTR) is based on the population served by the water supply system. For systems that serve 100,000 people or more, such as the SFPUC's Hetch Hetchy system, compliance with additional LT2ESWTR treatment technique requirements must be completed by April 1, 2012 (U.S. EPA, 2006). The result of this alternative is that the SFPUC would violate state and federal safe drinking water regulations, and delivery to customers after the compliance date could be prohibited.

Impact Analysis

Land Use

The No Project Alternative would not result in any land use changes or land use impacts, as there would be no construction or change of use at either site.

Visual Quality

This alternative would not directly result in any changes to the existing visual environment because no new facilities would be constructed, nor would any modifications to the existing sites be implemented, including the installation of new lighting at the Tesla Portal site. However, an indirect impact could occur in the event of a seismic event at the Tesla Portal. A seismic event could damage the existing disinfection facilities. Repair of these facilities could include exterior modifications or more likely, construction of new buildings. Construction of new buildings could affect views along a scenic route. However, this impact would be similar to the proposed project.

Geology, Soils and Seismicity

This alternative would not result in any direct impacts since no construction activities would occur. Potentially significant indirect environmental impacts from the No Project Alternative could occur if existing disinfection facilities at the Tesla Portal site were to be damaged during a seismic event. Damage to disinfection facilities at the Tesla Portal disinfection facilities could affect the ability of the SFPUC to provide treated water to its customers. Because of the potential failure of the existing disinfection facilities at the Tesla Portal site during a seismic event, an indirect significant impact could occur. This indirect impact could affect the ability of the SFPUC to provide treated water to its customers. This indirect impact is significant and an increase in impact relative to the proposed project.

Hydrology and Water Quality

There would be no construction or alteration at the project sites under the No Project Alternative, and as such, it would not have any direct environmental impacts. Similar to the other resource areas, this alternative could have indirect impacts should a seismic event occur. A seismic event could damage existing facilities that are not up to current safety standards, necessitating the construction of replacement facilities. The construction of replacement facilities could result in the alteration of site topography and increase the potential for erosion. However, like the proposed project, this would be a less-than-significant impact.

Biological Resources

This alternative would not result in any direct impacts on biological resources since new facilities would not be constructed and other associated site improvements would not be implemented. However, if existing disinfection facilities were to be damaged during a seismic event, significant indirect impacts would be expected. These impacts would be associated with construction of replacement facilities, which could affect special status species or their habitat. Nonetheless, the indirect biological resource impacts would be expected to be similar to the proposed project.

Cultural Resources

This alternative would not involve any direct impacts since there would be no construction associated with its implementation. However, if the existing disinfection facilities were to be damaged during a seismic event, construction of replacement facilities may result in discovery of or effects on cultural resources. This indirect impact would be similar to the proposed project.

Traffic, Transportation, and Circulation

This alternative would not result in any increases in traffic in the project area compared to existing conditions and, thereby, would not have any direct traffic impacts. If existing disinfection facilities were to be damaged during a seismic event, indirect impacts from construction of replacement facilities would be expected to be less than significant, like the proposed project.

Air Quality

This alternative would not result in any direct impacts on air quality since no additional emissions would occur over what currently exists. However, if the existing disinfection facilities were to be damaged during a seismic event, indirect significant impacts could occur. These indirect impacts would be associated with emissions from construction equipment used for construction of replacement facilities. However, these indirect impacts would be similar to those of the proposed project.

Noise and Vibration

This alternative would not directly result in any changes in the existing environment and would not, therefore, result in any direct impacts. However, indirect impacts could occur if the existing disinfection facilities would be damaged during a seismic event. Replacement of disinfection facilities would be expected to result in construction activities at the Tesla Portal site. Compared to the proposed project this would result in similar noise impacts.

Public Services and Utilities

The No Project Alternative would not construct new structures, implement any improvements, or make any changes at either project site. Consequently, it would not have any direct environmental impacts. This alternative could have indirect impacts if a seismic event were to take place. A seismic event could damage existing facilities that are not up to current safety standards, which could affect the SFPUC's ability to deliver water to its customers and require the construction of replacement facilities. The construction of replacement facilities could result in the production of construction debris and materials. However, as with the proposed project, this would be a less-than-significant impact.

Agricultural Resources

No construction would occur with this alternative and it would not have direct impacts on agricultural resources. Even if a seismic event damages existing disinfection facilities not up to current safety codes, requiring the construction of replacement facilities, this alternative would not have indirect impacts on agricultural resources. Construction of new facilities would be permitted at either site under the existing agricultural land use and zoning designations. Furthermore, construction of replacement facilities would not preclude agricultural activities from occurring on the undeveloped portion of either site. Indirect impacts of this alternative would be comparable to the proposed project.

Hazards

This alternative would not result in any direct hazard impacts because it would not construct new facilities or implement other associated site improvements. However, if existing disinfection facilities were damaged during a seismic event, this alternative would be expected to have less-than-significant

indirect impacts related to construction of replacement facilities, similar to the proposed project. Energy Resources

Given there would be no construction associated with this alternative, it would not produce any direct impacts. Should the existing disinfection facilities be damaged during a seismic event, construction of replacement facilities may result in temporary and long-term increased energy consumption. Relative to the proposed project, these indirect impacts would be similar to the proposed project.

Conclusions

- The No Project Alternative (Status Quo) would reduce potentially significant, but mitigable direct impacts associated with construction and operation of the proposed project, including, alteration of views as viewed from a scenic route and nighttime light and glare at the Tesla Portal site, impacts on biological and cultural resources, and noise, and air quality impacts. This alternative would also avoid the project's contribution to the SFPUC's WSIP potentially significant and unavoidable program-level impacts associated with growth inducement. However, under the No Project Alternative (Status Quo), if existing disinfection facilities at the Tesla Portal site were to become damaged during a seismic event, impacts similar to the proposed project, or potentially greater since facility replacement would occur during emergency conditions, would be expected. Damage to existing disinfection facilities resulting from a seismic event could also affect the SFPUC's ability to deliver water to meet demands in the Sunol Valley, Bay Division, Peninsula, and San Francisco sub-regions of its regional water service area. The No Project Alternative (Status Quo) would not meet any of the project objectives and would not meet contractual obligations to LLNL. Furthermore, under the No Project Alternative (Status Quo), the SFPUC would not comply with LT2ESWTR.[1]

[1] Lack of compliance with LT2ESWTR would make the SFPUC subject to monitoring, testing, and treatment violations (71 Fed. Reg. 653 [2006]) According to the Federal Register Vol. 71, No. 3, Thursday, January 5, 2006, beginning on page 653, National Primary Drinking Water Regulations: Long Term 2 Enhanced Surface Water Treatment Rule, public water systems (PWSs) are required "to provide a Tier 3 public notice for violation of monitoring and testing procedure requirements, including the failure to collect one or two source water Cryptosporidium samples. If a PWS fails to collect three or more Cryptosporidium samples, other than in specifically exempted situations the PWS must provide a Tier 2 special public notice. Violations for failing to monitor persist until the State determines that the PWS has begun sampling on a revised schedule that includes dates for the collection of missed samples." Further, "Failure by a PWS in any month to demonstrate treatment...equal to or greater than its Cryptosporidium treatment requirements is a treatment technique violation. This violation lasts until the PWS demonstrates that it is meeting criteria for sufficient treatment credit to satisfy its Cryptosporidium treatment requirements."
Tier 1 public notifications are for violations and situations with significant potential to have serious adverse effects on human health as a result of short-term exposure. Notice is required within 24 hours of the violation. Tier 2 public notifications are for other violations and situations with potential to have serious, but not immediate, adverse effects on human health. Notice is required within 30 days, or as soon as possible, with extension of up to three months for resolved violations at the discretion of the State or primacy agency. Tier 3 public notifications are for all other violations and situations not included in Tier 1 and Tier 2. Notice is required within 12 months of the violation, and may be part of a single annual report, including in some cases the annual CCR already required by the U.S. EPA (U.S. EPA Website, accessed 2008).

9.3.2 Alternative 2: No Project Alternative (Compliance with Safe Drinking Water Regulations)

Description

Under this No Project Alternative, none of the project elements would be implemented other than the construction of the 20,000-square-foot UV building at the Tesla Portal site, and there would be no construction at the Thomas Shaft site. This No Project Alternative is considered in this EIR because it is unrealistic that the SFPUC would proceed with the No Project Alternative (Status Quo) described in Section 9.3.1. Furthermore, other available water treatment processes to address compliance with LT2ESWTR were found to result in greater environmental impacts (see Section 9.4.3, Use Ozone Disinfection in Place of UV Disinfection). The Status Quo Alternative would not upgrade existing water treatment capabilities at the Tesla Portal, which would be in violation of state and federal safe drinking water regulations. While Alternative 2 would make water treatment improvements (the UV building), it would not include seismic upgrades to minimize the vulnerability of the existing disinfection facilities at the Tesla Portal site from the threat of a seismic event. Similar to the Status Quo Alternative, reasonably expected activities include the continued operation and maintenance of the Tesla Portal and Thomas Shaft facilities; continued deliveries of chemicals to the Tesla Portal and Thomas Shaft facilities; continued staffing of three full-time equivalent personnel at the Tesla Portal site; and continued discharge to the artificial wetland.

Impact Analysis

Land Use

This alternative would not result in any land use changes or land use impacts at the Thomas Shaft site, as there would be no construction or change of use at that site. It would likely require slightly less time to construct and possibly a smaller staging area at the Tesla Portal site, reducing the project's temporary land use disruption at the Tesla Portal site.

Visual Quality

No changes would occur to the existing visual environment at the Thomas Shaft site. Construction activities under this alternative would not last as long as under the project reducing the amount of time construction activities would affect the visual character and quality of the Tesla Portal site compared to the project. During the operational stage, this alternative's visual quality impacts would be reduced compared to the project as the Tesla Portal site would have two less buildings and less lighting. However, an indirect impact could occur in the event of a seismic event at the Tesla Portal and damage to existing disinfection facilities. Repair of these facilities could include exterior modifications, or more likely, construction of new buildings, and this construction could affect views along a scenic route resulting in an impact similar to the proposed project.

Geology, Soils and Seismicity

This alternative would not result in any direct impacts at the Thomas Shaft site since no construction activities would occur at this site. Potentially significant indirect environmental impacts from this

alternative could occur if existing disinfection facilities at the Tesla Portal site were to be damaged during a seismic event. Damage to disinfection facilities at the Tesla Portal disinfection facilities could affect the ability of the SFPUC to provide treated water to its customers. This indirect impact would be significant and an increase in impact relative to the proposed project.

Hydrology and Water Quality

There would be no construction or alteration at the Thomas Shaft site. Consequently, there would be no direct environmental impacts at this site. Compared to the proposed project, this alternative would have a reduced building footprint at the Tesla Portal site. Thus, less soil would be disturbed during construction, reducing the amount of eroded soil that could reach the artificial wetland and ephemeral drainage. While the project was determined to have less-than-significant construction impacts associated with erosion and sedimentation, comparatively, the construction impact of this alternative would be less than the proposed project. Additionally, this alternative would have more pervious surface area than the proposed project. The increase of pervious surfaces would reduce peak flow runoff rates and velocities compared to the project, resulting in reduced onsite and offsite erosion, and an incremental decrease in runoff volume and related stormwater pollutants.

Similar to the other resource areas, this alternative could result in indirect impacts should a seismic event occur and damage existing facilities. The construction of replacement facilities could result in the alteration of site topography and increase the potential for erosion; however, similar to the proposed project, this would be a less-than-significant impact.

Biological Resources

This alternative would not result in any direct impacts on biological resources at the Thomas Shaft site since improvements would not be implemented at this site. This alternative would reduce impacts on biological resources since the artificial wetland at the Tesla Portal site would not be affected and would continue to provide a year-round source of water; less California annual grasslands and ruderal/disturbed habitat would be disturbed (due to the reduced building footprint at the Tesla Portal site); and less special-status wildlife foraging and/or breeding habitat would be converted (due to the reduced building footprint at the Tesla Portal site) compared to the project. However, if existing disinfection facilities were to be damaged during a seismic event, significant indirect impacts to special status species or their habitat would be expected, similar to the proposed project.

Cultural Resources

This alternative would not involve any direct impacts at the Thomas Shaft site since there would be no construction at this site. However, this alternative would reduce the project's building footprint at the Tesla Portal site and the amount of ground disturbance. Consequently, this alternative may reduce potential direct effects on cultural resources during construction relative to the proposed project. Regardless, if the existing disinfection facilities were to be damaged during a seismic event, construction of replacement facilities may result in similar cultural resources impacts compared to the proposed project.

Traffic, Transportation, and Circulation

This alternative would result in a slight decrease in traffic in the project area compared to the proposed project due to less construction activities at the Tesla Portal site and no construction work at the Thomas Shaft site. If existing disinfection facilities were to be damaged during a seismic event, indirect impacts from construction of replacement facilities would be expected to be less than significant, like the proposed project.

Air Quality

This alternative would not result in any direct impacts on air quality at the Thomas Shaft site since no additional emissions would occur above current conditions. During construction, the reduced building footprint at the Tesla Portal site associated with this alternative would require less grading. The decrease in grading would consequently result in fewer emissions of fugitive dust during construction. The severity of air quality impacts would be reduced for this alternative compared to the proposed project since less grading would be required and less fugitive dust would be generated. Air quality impacts from operations would be the same as the proposed project. However, if the existing disinfection facilities were damaged during a seismic event, indirect significant impacts could occur, and indirect impacts associated with emissions from construction of replacement facilities would be similar to the proposed project.

Noise and Vibration

This alternative would not result in any direct changes in the existing environment at the Thomas Shaft site. Thus, it would not result in any direct impacts at this site. Noise impacts would be somewhat reduced at the Tesla Portal site due to the shorter construction period but would otherwise include similar construction noise impacts as the proposed project. However, impacts could occur if the existing disinfection facilities were damaged during a seismic event and the facility needed to be replaced; noise impacts due to construction of replacement facilities would be similar to the proposed project.

Public Services and Utilities

This alternative would not have any direct environmental impacts at the Thomas Shaft site, as it would not implement any improvements at this site. The new UV building would be built within the SFPUC's existing property and would not affect offsite utility services. In addition, construction of the new UV building at the Tesla Portal site would not interrupt service to existing water supply customers. The system would be shutdown during a regularly scheduled maintenance shutdown, which would allow for the tie-in to the new facilities at the Tesla Portal site. However, no interruption to SFPUC water customers would result, as they would continue to be served by other system sources. At the Thomas Shaft site, no on or offsite utilities would be affected. Therefore, potential impacts to existing regional and local public utilities would be less than significant This alternative could have indirect impacts if a seismic event were to take place and damage existing facilities, which could affect the SFPUC's ability to deliver water to its customers and require the construction of replacement facilities. The construction of replacement facilities could generate construction debris and materials; however, similar to the proposed project, this impact would be less than significant.

Agricultural Resources

No construction would occur with this alternative at the Thomas Shaft site and it would not have direct impacts on agricultural resources at this site. The construction of only the 20,000 square foot UV building under this alternative would result in a somewhat decreased footprint relative to the project. Accordingly, a larger portion of the Tesla Portal site would continue to be available for cattle grazing. Thus, relative to the proposed project, this alternative would allow for greater potential for grazing on the site.

Should a seismic event damage existing disinfection facilities not up to current safety codes, and require construction of replacement facilities, this alternative would not have indirect impacts on agricultural resources. Construction of replacement facilities would not preclude agricultural activities from occurring on the undeveloped portion of either site, and indirect impacts of this alternative would be comparable to the proposed project.

Hazards

This alternative would not result in any direct hazard impacts at the Thomas Shaft site because it would not construct new facilities or implement other associated improvements at this site. Potential hazard impacts (both construction and operational) at the Tesla Portal site would be similar to the proposed project. However, if existing disinfection facilities were damaged during a seismic event, this alternative would be expected to have less-than-significant indirect impacts related to construction of replacement facilities, similar to the proposed project. Futhermore, depending on the strength of a seismic event, there is the possibility it could cause a release of disinfection material. The disinfection material, Sodium Hypochlorite 12.5%, is a hazardous material. It is stored within tanks located inside a secondary containment area, which should contain any leaks cause by a seismic event. However, the secondary containment could leak during a seismic event, depending on its severity and magnitude. Regardless, due to its nature, Sodium Hypochlorite 12.5%, would not persist in the environment or migrate into the groundwater. It is the type of chemical that would most likely dissipate naturally. Thus, while it could be released into the environment, the chances of it causing substantial damage are low. Nonetheless, it would be an increased indirect impact relative to the project.

Energy Resources

Given there would be no construction associated with this alternative at the Thomas Shaft site, it would not produce any direct impacts at this site. There would be somewhat reduced energy impacts since fewer facilities would be built and less energy would be needed (both for construction and operation) compared to the proposed project. Should existing disinfection facilities be damaged during a seismic event, construction of replacement facilities may result in temporary and operational increased energy consumption, and impacts would be similar to the proposed project.

Conclusions

- The No Project Alternative (Compliance with Safe Drinking Water Regulations) would reduce potentially significant but mitigable direct impacts associated with construction and operation of the proposed project since fewer facilities would be built. These reduced impacts include alteration of views as viewed from a

scenic route and nighttime light and glare at the Tesla Portal site, impacts on biological and cultural resources, and noise, and air quality impacts. This alternative would also avoid the project's contribution to the SFPUC's WSIP's potentially significant and unavoidable program-level impacts associated with growth inducement. However, under this alternative, if existing disinfection facilities at the Tesla Portal site were damaged during a seismic event, impacts similar to the proposed project, or potentially greater, since facility replacement would occur during emergency conditions, would be expected. Damage to existing disinfection facilities resulting from a seismic event could also affect the SFPUC's ability to deliver water to meet demands in the Sunol Valley, Bay Division, Peninsula, and San Francisco sub-regions of its regional water service area. This alternative would construct new water treatment facilities, and therefore, would meet the project objective related to compliance with LT2ESWTR. However, it would not meet contractual obligations to LLNL and it would not seismically upgrade existing facilities.

9.3.3 Alternative 3: Continue Water Source to Artificial Wetland at Tesla Portal Site

Description

Under this alternative, the SFPUC would continue to provide a year round water source to the artificial wetland at the Tesla Portal site. The source of water would change from existing analyzer equipment to the new analyzer equipment that would be located adjacent to the wetland area. The amount of water provided would be roughly the same amount that currently feeds the wetland area. During regularly scheduled shutdowns at the facility, which are up to 45 days at a time, water would not be provided, similar to existing conditions. Under this alternative, all other aspects of the proposed project at the Tesla Portal and Thomas Shaft sites would be implemented as described in Chapter 3. This alternative would meet all project objectives.

Impact Analysis

Biological Resources

This alternative would reduce impacts on biological resources since a permanent, year-round source of water would be provided to the artificial wetland at the Tesla Portal site. Although the artificial wetland is not considered a jurisdictional feature by state or federal agencies, implementation of the project would result in the loss of wetland functions and values (i.e., the only year-round source of water in the project area and surrounding valley bottom), and would substantially degrade or diminish habitat values for dependent plant and wildlife species. The proposed project would discontinue the water source for the artificial wetland area, when water from the analyzer equipment at Tesla Portal is no longer discharged to the artificial wetland area. The artificial wetland has little natural water source other than natural runoff and discharges from the Tesla Portal facility; therefore, the long-term effect of this action would be loss of most or all of the artificial wetland, resulting in a potentially significant impact that could be mitigated to less-than-significant levels. Thus, compared to the proposed project, this alternative would have reduced impacts.

Conclusion

- Alternative 3: Continue Water Source to Artificial Wetland at Tesla Portal Site would meet all of the project objectives and, therefore, would be expected to have similar growth inducement impacts compared to the proposed project. This alternative would contribute to the SFPUC's WSIP's potentially significant and unavoidable program-level impacts associated with growth inducement. This alternative would avoid impacts associated with permanent loss of 0.308 acre of artificial wetland at the Tesla Portal site and the associated loss of habitat value to dependent plant and wildlife species that are identified as potentially significant but mitigable under the proposed project. Other potentially significant but mitigable biological resources impacts during project construction would be the same as the proposed project under this alternative. This alternative would implement the Lawrence Livermore Water Quality Improvements at the Thomas Shaft site as described in Chapter 3. Therefore, the impact analysis and conclusions presented in Chapter 4 related to the Thomas Shaft site would be the same under this alternative, and are not discussed further in this section. Given that this alternative would implement all the same improvements as the project (excluding discontinuing the permanent, year round water supply to the artificial wetland at the Tesla Portal site), its potential impacts would be the same as the project's potential impacts for the following resource areas:

  - Land Use
  - Visual Quality
  - Geology, Soils, and Seismicity
  - Hydrology and Water Quality
  - Cultural Resources
  - Traffic, Transportation, and Circulation
  - Air Quality
  - Noise and Vibration
  - Public Services and Utilities
  - Agricultural Resources
  - Hazards
  - Energy Resources

9.3.4 Alternative 4: Combine Office/Control Building and UV Building at Tesla Portal Site

Description

This alternative proposes to combine the 3,500-square-foot Office/Control Building and the 20,000-square-foot UV Building in a single, two-story structure at the Tesla Portal site instead of housing each facility in two separate single-story buildings, as they would be under the proposed project. Under this alternative, the total building footprint would be smaller than the proposed project; however, the building would be taller than the proposed one-story structures under the project. In addition, the Chemical Process Building and other improvements at the Tesla Portal site as well as the Lawrence Livermore Water Quality Improvements at the Thomas Shaft site would be implemented as described in Chapter 3. This alternative would meet all project objectives.

Impact Analysis

Visual Quality

Construction activities under this alternative would be similar to the project and would have the same significant, but mitigable affects on the visual character and quality of the project sites as they would under the project.

I-580 is a state designated scenic route. The existing structures at the Tesla Portal site are somewhat visible from I-580, although much of the existing facility is shielded from view by trees. During the operational phase, this alternative would have a potentially greater visual impact than the project because the Office/Control Building and the UV Building would be combined into a single, two-story structure at the Tesla Portal site, which would be taller and more visible than the one-story structures proposed by the project.

Hydrology and Water Quality

The construction of a single multi-purpose building would reduce the building footprint at the Tesla Portal site as compared to the proposed project. Potential soil erosion to the artificial wetland and ephemeral drainage would be reduced under this alternative because less soil would be disturbed during construction. While the project was determined to have less-than-significant impacts associated with erosion and sedimentation during construction, comparatively this alternative would have less erosion and sediment potential than the proposed project during construction.

During operation, this alternative would have more pervious surface area than the proposed project. However, the increase in pervious surface area would minor, given that the majority of the site would remain pervious with its construction. Nonetheless, the increase of pervious surfaces would reduce peak flow runoff rates and velocities compared to the project, resulting in reduced onsite and offsite erosion, and an incremental decrease in runoff volume and related stormwater pollutants.

Biological Resources

Under this alternative, construction staging and other construction-related activities would be expected to be of a similar size and nature as the proposed project, as all the same features would be built, even though the Office/Control Building would be combined with the UV Building in a single, two-story structure rather than constructing two separate single-story buildings. Consequently, this alternative would be expected to result in similar construction disturbance of the ephemeral drainage, California annual grasslands, and ruderal/disturbed habitat, as well as similar temporary loss of foraging and/or breeding habitat for some or all of the special status species known to occur, or with potential habitat present at the project sites. Because the footprint of the permanent facilities would be 3,500 square feet less than they would be under the proposed project during operations, this alternative would convert less special-status wildlife foraging and/or breeding habitat than the proposed project, reducing impacts on special-status wildlife compared to the proposed project.

Cultural Resources

Under this alternative, the amount of ground disturbance would be slightly less (3,500 square feet) than for the proposed project and the potential effects during construction on cultural resources may be reduced accordingly relative to the proposed project. As with the project, after this alternative is built, its operation would not have the potential to affect historical, archaeological or paleontological resources.

Air Quality

During construction, the reduced building footprint at the Tesla Portal site associated with this alternative would require less grading. The decrease in grading would consequently result in fewer emissions of fugitive dust during construction. The severity of air quality impacts would be reduced for this alternative compared to the proposed project since less grading would be required and less fugitive dust would be generated. Air quality impacts from operations would be the same as the proposed project.

Agricultural Resources

Construction and operation of one less building would result in a decreased footprint relative to the project. Accordingly, 3,500 square feet of the Tesla Portal site would continue to be available for cattle grazing. Thus, this alternative would slightly increase the agricultural productivity potential of the site relative to the proposed project.

Conclusion

- Alternative 4: Combine Office/Control Building and UV Building at Tesla Portal site would meet all of the project objectives and, therefore, would be expected to have similar growth inducement impacts compared to the proposed project. This alternative would contribute to the SFPUC's WSIP's potentially significant and unavoidable program-level impacts associated with growth inducement. This alternative would reduce the severity of impacts associated with biological and cultural resources, and air quality in the proposed project area; these impacts would remain potentially significant, but mitigable as they are under the proposed project. Additionally, this alternative would reduce the severity of the project's erosion and sedimentation potential (a less than significant impact). It would also slightly increase the amount of land available for cattle grazing at the Tesla Portal site. However, this alternative could result in greater visual

impacts because of the increased building height. Because this alternative would implement all project features identified in the project description in Chapter 3 with the exception that it would reduce the development footprint of the project, it would be expected to result in similar impacts as the project for the following resource areas:

- Land Use
- Geology, Soils, and Seismicity
- Traffic, Transportation, and Circulation
- Noise and Vibration
- Public Services and Utilities
- Hazards
- Energy Resources

9.3.5 Alternative 5: Retrofit of Existing Tesla Portal Hypochlorite Station Building

Description

Under this alternative, the SFPUC would retrofit the existing building that contains the Tesla Portal Hypochlorite Station rather than construct a new Chemical Process Building. This alternative would reduce the building footprint at the Tesla Portal site by approximately 14,000 square feet. The Tesla Portal facility must be capable of providing disinfection to the Hetch Hetchy flows throughout the construction period. Consequently, a temporary chemical feed facility would be constructed to inject sodium hypochlorite into the Coast Range Tunnel at the same location as the existing injection system to maintain the disinfection function as well as the required monitoring, sampling, and reporting functions. The Thomas Shaft Chlorination Facility would continue to provide back up disinfection.

The temporary chemical feed facility would include an approximately 20-foot-wide by 20-foot-long by 12-foot-high building located approximately southeast of the existing feed building over the top or nearly over the top of the Coast Range Tunnel. The facility would have main and back-up power and communications to house and protect the pumps, pumping control equipment, feed lines, and monitoring equipment from weather, for security, and to allow for uninterrupted operation during construction. Temporary tanks and connections that provide for the required chemical storage and allow for chemical deliveries would also be provided. Since these temporary facilities must allow full access for operations and water quality personnel, the paved road would still be used for chemical deliveries and vehicle access. After the existing building containing the Tesla Portal Hypochlorite Station is retrofitted, demolition of the temporary chemical feed facility would generate approximately 200 cubic yards of building waste material.

Upgrades under this alternative that would meet (fully or partially) the project objective related to seismic reliability and safety consist of the following:

- Replace tanks, piping, and major process equipment
- Relocate the domestic/fire water pumps to allow full-time use
- Replace panels and uninterruptible power supply system to meet the applicable codes
- Repair damaged trusses
- Replace concrete slab, foundation, and containment area
- Install fire protection system (San Francisco Water Team, 2001).

The UV Building, Office/Control Building and other improvements at the Tesla Portal site as well as the Lawrence Livermore Water Quality Improvements at the Thomas Shaft site would be implemented as described in Chapter 3.

This alternative would not be able to accommodate the pH adjustment equipment and, therefore, that project objective would not be met, and a building for this equipment may be needed in the future. Furthermore, it should be noted that a previous structural and engineering evaluation of the current building and systems (San Francisco Water Team, 2001) concluded that upgrades to the current building and systems "cannot increase the reliability and performance comparable to a new facility." Thus, this alternative would not have the reliability and performance capability of a new facility.

Impact Analysis

Visual Quality

Construction activities under this alternative would be similar to the project and would have the same significant but mitigable affects on the visual character and quality of the project sites as they would under the project. During the operational stage, the visual quality impacts associated with this alternative would be reduced by constructing one less building than the proposed project.

Hydrology and Water Quality

The temporary disinfection facility would have a reduced footprint compared to the Chemical Process Building, as such, this alternative would require less grading relative to the project. Potential soil erosion to the artificial wetland would be reduced under this alternative because of the smaller area of disturbance during construction. Although the project was determined to have less-than-significant impacts associated with erosion and sedimentation during construction, comparatively, this alternative would have less erosion and sediment potential than the proposed project during construction.

During operation, this alternative would have more pervious surface area than the proposed project. However, the increase in pervious surface area would be minor, given that the majority of the site would remain pervious with its construction. Nonetheless, the increase of pervious surfaces would reduce peak

flow runoff rates and velocities compared to the project, resulting in reduced onsite and offsite erosion, and an incremental decrease in runoff volume and related stormwater pollutants. After the existing building containing the Tesla Portal Hypochlorite Station is retrofitted, demolition of the temporary chemical feed facility would generate approximately 200 cubic yards of building waste material. Demolition of the temporary chemical feed facility has the potential to impact water quality by increasing erosion and sedimentation. Construction activities would comply with SFPUC Construction Measure #3, minimizing erosion and sedimentation; therefore, demolition of the temporary facility would have less-than-significant impacts on water quality. While the project was determined to have less-than-significant impacts associated with erosion and sedimentation, comparatively, this alternative would have less erosion and sediment potential than the proposed project.

Biological Resources

With this alternative, construction staging and other construction-related activities would be relatively the same as the proposed project. However the building footprint would be reduced by about 14,000 square feet compared to the proposed project; therefore, this alternative would disturb less California annual grasslands and ruderal/disturbed habitat than the project, and would not convert as much special-status wildlife foraging and/or breeding habitat as the project would. Therefore this alternative would reduce impacts on special-status wildlife compared to the proposed project.

Cultural Resources

Implementation of this alternative would reduce the project's building footprint and the amount of ground disturbance. Consequently, this alternative may reduce potential effects on cultural resources during construction relative to the proposed project. As with the project, after this alternative is built, its operation would not have the potential to affect historical, archaeological, or paleontological resources.

Air Quality

The reduced building footprint at the Tesla Portal site associated with this alternative would require less grading. However, it would require demolition of the temporary facility. Fugitive dust emissions from demolition are expected to be minor. The net severity of air quality impacts would still be reduced for this alternative compared to the proposed project since less grading would be required and less fugitive dust would be generated during construction. Air quality impacts from operations would be the same as the proposed project.

Public Services and Utilities

This alternative would be expected to result in similar impacts as the project with the exception that it would generate a slightly greater amount of solid waste from demolition of the temporary feed facility.

Agricultural Resources

The construction of one less building under this alternative would result in a decreased footprint of approximately 14,000 square feet relative to the project. Accordingly, more of the Tesla Portal site would continue to be available for cattle grazing. Thus, this alternative could increase the potential for grazing on the site relative to the proposed project.

Conclusion

- Alternative 5: Retrofit of Existing Tesla Portal Hypochlorite Station Building would be expected to have similar growth inducement impacts compared to the proposed project, and would contribute to the SFPUC's WSIP's potentially significant and unavoidable program-level impacts associated with growth inducement. This alternative site configuration would reduce the severity of some of the impacts associated with the proposed project but would not reduce the need for mitigation or change the determinations of significant but mitigable impacts. It would reduce the amount of erosion, dust, and temporary California annual grassland and ruderal/disturbed habitat disturbance during construction. During operations, it would have reduced visual, erosion, and water quality impacts; would not convert as much special-status wildlife foraging and/or breeding habitat as the project; and would increase the agricultural productivity potential (grazing) of the site relative to the proposed project. This alternative would not be able to accommodate the pH adjustment equipment and, therefore, that project objective would not be met, and a building for this equipment may be needed in the future. Furthermore, this alternative would not have the reliability and performance capability of a new facility. Due to the minor changes associated with this alternative compared to the proposed project, it would be expected to result in similar impacts as the project for the following resource areas:

  - Land Use
  - Geology, Soils, and Seismicity
  - Traffic, Transportation, and Circulation
  - Noise and Vibration
  - Hazards
  - Energy Resources

TABLE 9-3

COMPARISON OF ALTERNATIVE PROJECT IMPACTS TO THE PROPOSED PROJECT

Category of Potential Significant Environmental Impact	Proposed Project	No Project Alternative (Status Quo)	No Project Alternative (Compliance with Safe Drinking Water Regulations)	Continue Water Source to Artificial Wetland at Tesla Portal Site Alternative	Combine Office/Control Building and UV Building at Tesla Portal Site Alternative	Retrofit of Existing Tesla Portal Hypochlorite Station Building Alternative
Land Use	Effects found to be less- than-significant.	No impacts since there would be no construction or change of use.	No impacts at the Thomas Shaft site since no construction or change of use would occur at this site. Reduction in the project's temporary land use disruption at the Tesla Portal site.	Same impacts as the project since only difference is that the water supply to the artificial wetland area at the Tesla Portal site would not be cut-off.	Same impacts as the project because the only difference is that the Office/Control Building and the UV Building would be combined in a single, two-story structure at the Tesla Portal site.	Same impacts as the project because of the minor differences associated with the building retrofit and construction of one less building at the Tesla Portal site.
Visual Quality	Permanent adverse impacts on scenic vistas or resources found to be significant, but mitigable to less-than-significant levels at the Tesla Portal site. Operational nighttime light and glare found to be significant, but mitigable to a less-than-significant level at the Tesla Portal site.	No impacts since there would be no construction. If the existing disinfection facilities were to be damaged during a seismic event, there could be direct mitigable impacts similar to the proposed project from the construction of replacement facilities.	No impacts at the Thomas Shaft site since no construction would occur at this site. Reduction in the amount construction activities and temporary affects to visual character and quality of the Tesla Portal site. Permanent visual impacts would be somewhat reduced because of the construction of fewer buildings and installation of less lighting at Tesla Portal.	Same impacts as the project because the only difference is that the water supply to the artificial wetland area at the Tesla Portal site would not be cut-off.	Potentially somewhat greater visual impact since the Office/Control Building and the UV Building would be combined in a single, two-story structure at the Tesla Portal site which would be taller and more visible than the one-story structures proposed by the project.	Visual impacts would be somewhat reduced because of the construction of one less building at Tesla Portal.

Similar impacts as the project because of the minor differences associated with the building retrofit and construction of one less building at the Tesla Portal site.

9.4 Possible Alternatives Considered, but Rejected

This section presents 11 alternatives that were considered as alternatives to the proposed project, but were not carried forward for further consideration because they would clearly result in environmental impacts greater than those of the proposed project and/or because they did not meet most of the project objectives, which are listed above in the introduction to this chapter and in Chapter 3. These are therefore not considered CEQA alternatives.

9.4.1 Locate UV Disinfection Facility at Moccasin Reservoir

Under this alternative, a UV system similar to the one that would be installed at the Tesla Portal site would be installed at Moccasin Reservoir, a Hetch Hetchy component located in Tuolumne County. Due to site topography and system hydraulics, the UV reactor building would have to be constructed below the existing ground surface to eliminate the need to pump water when Moccasin Reservoir is at its minimum operating water surface elevation. Implementation of this alternative would require draining the reservoir during construction or constructing the facility underwater. This alternative would install an effluent line to convey treated water back to the Hetch Hetchy system and an effluent weir to make sure that the UV lamps would stay submerged under all operating conditions.

This alternative would achieve the objectives of the project. However, this alternative would create greater construction-related impacts than the proposed project, as more excavation would be required for the UV building, the effluent line, and the effluent weir. Among other potential impacts, increased excavation would generate more noise, greater amounts of construction-related air pollutants, greater consumption of energy, greater total numbers of truck trips, and pose greater potential threats to biological resources. Greater operational impacts would also result from the pumping equipment that would be needed.

9.4.2 Locate UV Disinfection Facility at the Oakdale Portal

This alternative would install a UV system similar to one that would be installed at the Tesla Portal site at Oakdale Portal, where the San Joaquin Pipelines begin, in Tuolumne County. It would require new medium voltage power supply to power the facility. While this alternative would achieve the project objectives, it would create greater construction-related and long-term environmental impacts than the proposed project. New power lines would have to be erected along several miles of land currently used for cattle grazing. Extensive road improvements, much greater than those that would be undertaken with the proposed project, would be required to allow truck access to the facility. Lastly, there is no onsite staff at this facility, and a greater number of personnel would have to be hired than would be the case under the proposed project.

9.4.3 Use Ozone Disinfection in Place of UV Disinfection

Under this alternative, instead of UV disinfection, ozone would be used to sanitize drinking water at the Tesla Portal site by injecting the water with ozone. This would involve construction of an approximately 3,750-square-foot liquid oxygen storage building, an approximately 4,900-square-foot building for ozone generation, and an extensive serpentine piping system. This alternative would achieve the objectives of the project, but it would have greater environmental impacts. Energy consumption under this alternative

would be roughly four times the amount used by the UV facility (SFPUC, 2006). Increased hazards associated with liquid oxygen consist of over-pressurization due to expansion of small amounts of liquid into large volumes of gas in inadequately vented equipment; oxygen enrichment of the surrounding atmosphere; and the possibility of a combustion reaction if the oxygen is permitted to contact a non-compatible material.[2] Although this alternative would have a smaller building footprint at the Tesla Portal site than the project, its construction would result in a greater total ground disturbance at the Tesla Portal site due to the extensive piping system that would be required. In addition, this alternative would require more truck deliveries than the proposed project.

9.4.4 Use Ozone Preoxidation in Addition to UV Disinfection

This alternative would use ozone to oxidize water prior to the water undergoing UV disinfection. This would involve construction of an approximately 3,750-square-foot liquid oxygen storage building, an approximately 5,500-square-foot building for ozone generation, and degassing facilities. The UV system would remain the same as that of the proposed project. This alternative would achieve the objectives of the project. However, it would create greater construction-related impacts than the proposed project, as additional facilities would be constructed besides the ones already proposed under the project. This alternative would have increased hazards impacts due to the use of liquid oxygen, as described above. In addition, this alternative would require more truck deliveries than the proposed project.

9.4.5 New UV Building and Percolation Pond at Thomas Shaft

This alternative would install a UV system in a new approximately 300 square foot building within an existing fenced area near the Thomas Shaft and a concrete percolation pond. This alternative was originally the proposed project but was redesigned to minimize potential environmental impacts by eliminating new building construction for the UV system, and minimizing the construction footprint of the percolation pond by using a percolation tank instead. This alternative was rejected because it would disturb a larger area of the site, compared to the proposed project, and result in greater environmental impacts. Since this alternative was originally the proposed project, it accordingly would meet the project objectives.

9.4.6 UV Disinfection System Plus Booster Chlorine at Thomas Shaft

This alternative would install a UV system in a new approximately 300 square foot building within an existing fenced area near the Thomas Shaft and a new booster chlorination system and an offline monitoring system. The booster chlorination provides virus inactivation through free chlorine contact time (CT) from transmission lines during an emergency event when chlorination that occurs at the Tesla Portal site goes offline due to a system failure. It should be noted that the option of booster chlorination would not be needed if LLNL switches to an alternate water supply source when the supply of properly treated water is interrupted due to a chlorination system failure at the Tesla Portal site. This alternative would meet project objectives, but it was rejected because it would disturb a larger area of the Thomas Shaft site and result in greater environmental impacts.

[2] Harvard School of Engineering and Applied Sciences, Physics Department and Department of Earth and Planetary Sciences Safety Committee website, accessed May 23, 2008.

9.4.7 CT Tanks System at Thomas Shaft

Under this alternative, all project components proposed at the Tesla Portal site would be constructed and additional *Giardia* inactivation would occur at Thomas Shaft in two CT tanks. At the Thomas Shaft site, this alternative would construct a CT tanks system consisting of two identical tanks, a booster pump station, and tank inlet and outlet chlorine monitoring stations. With two tanks, an effective contact volume is provided assuming that each tank maintains an operating level at least half-full. The booster pump station would consist of two pumps that deliver water from either CT tank through the transmission line and to the LLNL Site 300. A booster chlorine system would be constructed to feed additional chlorine as needed. This alternative would meet project objectives, but it was rejected because it would disturb a larger area of the Thomas Shaft site and result in greater environmental impacts.

9.4.8 CT Tanks System plus Booster Chlorine at Thomas Shaft

This alternative is similar to the CT Tanks System alternative with the exception that a new booster chlorination system would also be constructed at Thomas Shaft to provide *Giardia* inactivation via the CT tanks during an emergency event when chlorination that occurs at the Tesla Portal site goes offline due to a system failure. The option of booster chlorination would not be needed if LLNL switches to an alternate water supply source when the supply of properly treated water is interrupted due to a chlorination system failure at the Tesla Portal site. This alternative would meet project objectives, but it was rejected because it would disturb a larger area of the Thomas Shaft site and result in greater environmental impacts.

9.4.9 LLNL Transmission Line Chlorination

Under this alternative, drinking water disinfection would occur at the Tesla Portal site as proposed by the project. Accordingly, all project components proposed at the Tesla Portal site would be constructed. At the Thomas Shaft site, *Giardia* and other viruses would be inactivated through free chlorine disinfection in the Coast Range Tunnel (from Tesla Portal to Thomas Shaft) and the 10-inch transmission line (from Thomas Shaft to LLNL Site 300). This alternative would construct an onsite chlorine monitoring station at Thomas Shaft and an offsite chlorine monitoring station. This alternative would meet project objectives, but it was rejected because it would disturb a larger area of the Thomas Shaft site, require the construction of offsite facilities, and result in greater environmental impacts.

9.4.10 LLNL Transmission Line Chlorination with Booster Chlorine

This alternative is similar to the LLNL Transmission Line Chlorination alternative with the exception that a new booster chlorination system would also be constructed at Thomas Shaft to provide *Giardia* inactivation during an emergency event when chlorination that occurs at the Tesla Portal site goes offline due to a system failure. The option of booster chlorination would not be needed if LLNL switches to an alternate water supply source when the supply of properly treated water is interrupted due to a chlorination system failure at the Tesla Portal site. This alternative would meet project objectives, but it was rejected because it would disturb a larger area of the Thomas Shaft site, require the construction of offsite facilities, and result in greater environmental impacts.

9.4.11 All Facilities Built at Thomas Shaft Site

This alternative would install all the facilities proposed at the Tesla Portal site at the Thomas Shaft site. This alternative was rejected because the new facilities would need to be connected to the Coast Range Tunnel which is very deep at the Thomas Shaft site (approximately 300 feet) and, therefore, water would have to be pumped to the surface for treatment requiring installation of a pump station, resulting in greater potential environmental impacts, associated with air quality; cultural resources; hydrology and water quality; geology, soils, and seismicity, noise and vibration; and, energy resources.

This alternative would not meet project objectives because the Hetch Hetchy water system would no longer have a backup chlorination facility to treat water, as is currently required, if all the facilities proposed were to be built at Thomas Shaft site. This would eliminate SFPUC's flexibility in making adjustments to disinfection requirement in time prior to distribution to the regional customers. This alternative would also affect current water distribution to LLNL Site 200 from the Mocho Shaft, making that water non-potable and, therefore, the SFPUC would not be able to meet contractual requirements for both Site 200 and Site 300.

9.5 Environmentally Superior Alternative

The CEQA Guidelines require the identification of an environmentally superior alternative to the proposed project (Section 15126.6[e]) if it is determined that the No Project Alternative would otherwise be the environmentally superior alternative. If so, then the EIR must also identify an environmentally superior alternative among the other project alternatives (Section 15126.6[e]).

Alternative 1, the No Project Alternative (Status Quo), would reduce all of the potentially significant, but mitigable impacts of the proposed project to a level of no impact. While this alternative would not result in any construction-related impacts, failure to take action would result in the continued seismic vulnerability of existing facilities at the Tesla Portal site. Moreover, earthquake damage could cause the release of Sodium Hypochlorite 12.5%, is a hazardous material. As described under the impact analysis for the Status Quo Alternative, such vulnerability makes the system susceptible to the damaging effects of earthquakes. Thus, it is reasonably foreseeable that the Status Quo Alternative would eventually lead to future environmental impacts associated with earthquake damage to the existing Tesla Portal Hypochlorite Station. Such earthquake damage could constitute a threat to human health and safety (e.g., disruption of water supply, and release of hazardous materials [Sodium Hypochlorite 12.5%]). Furthermore, the Status Quo Alternative would result in the failure of the SFPUC to comply with federal regulations regarding the reduction of *Cryptosporidium* and *Giardia* in drinking water, and also would prohibit the SFPUC from fulfilling a contractual agreement with Lawrence Livermore National Laboratory (LLNL) to supply LLNL Site 300 with drinking water.

Based on the comparison of alternatives in this section, Alternative 4 (Retrofit of Existing Tesla Portal Hypochlorite Station Building) would be the environmentally superior alternative because, in comparison to the other alternatives, it would have the potential to reduce the greatest amount of project impacts (visual quality, hydrology and water quality, biological resources, cultural resources, air quality, and agricultural resources), resulting in the fewest or least significant environmental effects. However, this alternative would not be able to accommodate the pH adjustment equipment and, therefore, that project objective would not be met, and a building for this equipment may be needed in the future. Furthermore,

it should be noted that a previous structural and engineering evaluation of the current building and systems (San Francisco Water Team, 2001) concluded that upgrades to the current building and systems "cannot increase the reliability and performance comparable to a new facility." Thus, this alternative would not have the reliability and performance capability of a new facility.

CHAPTER 1
Introduction

This Comments and Responses document has been prepared to respond to comments received on the Draft Environmental Impact Report (Draft EIR) for the San Francisco Public Utilities Commission's (SFPUC) San Joaquin Regional Water Quality Improvement Project (SJRWQIP) (State Clearinghouse No. 2007052109), which was published by the San Francisco Planning Department on August 25, 2008. The 45-day public review period for the document occurred between August 25 and October 8, 2008. The Draft EIR together with this Comments and Responses document constitute the Final EIR for the SJRWQIP.

The Draft EIR described the proposed SJRWQIP, identified the environmental impacts associated with the project, specified mitigation measures to reduce significant and potentially significant impacts, and analyzed and compared the environmental effects of four alternatives to the proposed project as required by the California Environmental Quality Act (CEQA).

This Comments and Responses document responds to the written and oral comments on the Draft EIR and revises the Draft EIR as necessary to provide additional clarity. This document has been distributed to the San Francisco Planning Commission, SFPUC, State Clearinghouse, agencies and persons who commented on the Draft EIR. The San Francisco Planning Commission will consider this document, along with the Draft EIR and any revisions to the Draft EIR based on the responses to comments, for certification as the Final EIR for the SJRWQIP. In the event of an appeal of the certification, the San Francisco Board of Supervisors will hear and decide on the appeal.

If the Planning Commission certifies the EIR, the SFPUC will consider the environmental evaluation in the Final EIR, and the associated Mitigation Monitoring and Reporting Program (MMRP), prior to its decision on the proposed project. The SFPUC will adopt CEQA findings and the MMRP at the project decision hearing.

This Comments and Responses document for the SJRWQIP includes:

- A list of all persons, organizations, and public agencies who submitted written comments on the Draft EIR and who testified at the public hearings on the Draft EIR held in San Joaquin County (City of Tracy) on September 16, 2008 and in San Francisco on September 18, 2008;

- Chapter 2 contains copies of the written comments received on the Draft EIR, along with a response to each comment, and copies of the transcripts from the public hearings on the Draft EIR, along with responses to oral comments made at the hearings; and

- Staff-initiated text changes to the Draft EIR are included in Chapter 3.

1.1 Comments on the Draft EIR and Responses to Comments

To facilitate the preparation of responses, each comment document (i.e., letter, email, or public hearing transcript) received on the Draft EIR was coded to identify the commenter and then divided into individual comments, which were numbered. Each comment document (i.e., letter or transcript) consists of a prefix indicating the commenter category (shown in Table 1-1) followed by the acronym of the agency/organization or the first five letters of the person's last name. For example, the comment letter received from the California Department of Fish and Game (a state agency) is coded S-CDFG. Within each comment document, the individual topics or issues raised are bracketed and numbered sequentially. Therefore in this example, the first comment in the letter received from the California Department of Fish and Game is coded S-CDFG-01 and is shown in the right margin of the letter.

TABLE 1-1
COMMENTER CATEGORIES

Category of Commenter	Coding Abbreviation
Federal Agency	F
State Agency	S
Local and Regional Agency	L
Citizen	C
Group	G

The Draft EIR was circulated for a 45-day public review period from August 25 to October 8, 2008. Agencies, organizations, and individuals who submitted written comments on the Draft EIR during the public review period are listed in Table 1-2. Individuals who spoke at the public hearing in Tracy on September 16 are also included in Table 1-2. Please note that no public comments were received at the Public Hearing held in San Francisco on September 18. The transcripts of both public hearings are provided in Chapter 2 for reference.

In cases where the response to the comment results in a change in the Draft EIR, the revised text, figures or tables are shown in the response to that comment. Additions are indicted by a double underline; deletions are indicated by "strike-out." For example: Edits to this text are ~~inserted~~ provided for clarity.

1.2 Staff-Initiated Text Changes to the Draft EIR

Additional edits to the Draft EIR are provided at the initiation of staff to clarify content, add additional information received after the release of the Draft EIR, or to correct content in the Draft EIR. These text changes are provided in Chapter 3 and indicate the page and paragraph to be revised and show the proposed change using double underline and strike-out, as described above. A description of the text changes is provided if necessary.

In addition, text changes that were made in response to a comment (and discussed in Chapter 2) are also reiterated in Chapter 3.

CHAPTER 2
Comments and Responses

This chapter includes a copy of each comment letter received on the Draft EIR followed by the corresponding response(s). The responses correspond to the numbers that appear in the margins of the comment letters and public hearing transcripts. As required by the California Environmental Quality Act (CEQA) Section 15132, the responses in this chapter are directed towards potentially significant environmental points raised by commenters during the review period.

The responses are intended to provide clarification and refinement of information presented in the Draft EIR, and in some cases, to correct or update information in the Draft EIR. Where the responses indicate additions or deletions to the text of the Draft EIR, additions are indicated in double underline and deletions are in ~~strike-out~~.

Dear Ms. Dean:

The California Department of Transportation (Department) appreciates the opportunity to have reviewed the Draft Environmental Impact Report (DEIR) for the proposed construction of the San Joaquin Regional Water Quality Improvement Project. This proposed project is to be located in the unincorporated San Joaquin County at two existing facility sites, the Tesla Portal site and the Thomas Shaft site along the SFPUC's regional water system. [01]

The Department has no comments at this time.

If you have any questions or would like to discuss our comments in more detail, please contact Kathy Selsor at (209) 948-7190 (e-mail: kathy_selsor@dot.ca.gov) or me at (209) 941-1921.

Sincerely,

Kathy Selsor for

San Francisco, CA 94103

Dear Ms. Dean:

Subject: Comments on Draft Environmental Impact Report for San Joaquin Regional Water Quality Improvement Project, SCH #2007052109, San Joaquin County

Department of Fish and Game (DFG) staff has reviewed the draft Environmental Impact Report (EIR) for the San Joaquin Regional Water Quality Improvement Project (Project). The San Francisco Public Utilities Commission (SFPUC) proposes to construct the above referenced Project. The proposed Project is located in unincorporated San Joaquin County at two existing facility sites, the Tesla Portal site and the Thomas Shaft site, along the SFPUC's regional water system. The Tesla Portal site includes Assessor's Parcel No. 253-160-02, Township 3S and Range 5E. The Thomas Shaft site includes Assessor's Parcel No. 251-330-10, Township 4S and Range 4E. At the Tesla Portal site, the existing building that contains the Tesla Portal Hypochlorite Station would be replaced with a new Chemical Process Building and Office/Control Building. An ultraviolet (UV) facility would be constructed, which would disinfect water using a series of UV light arrays. At the Thomas Shaft site, the Lawrence Livermore Water Quality Improvements would upgrade existing water treatment with a UV facility to meet disinfection requirements of the Surface Water Treatment Rule and the Long Term 2 Enhanced Surface Water Treatment Rule.

DFG, a Trustee Agency under the California Environmental Quality Act (CEQA), is responsible for the conservation, protection, and management of the State's biological resources. Pursuant to Fish and Game Code Section 1801, it is the policy of the State to encourage preservation, conservation, and maintenance of wildlife resources, including perpetuation of all species of wildlife for their intrinsic and ecological values. In addition, pursuant to Fish and Game Code Section 1802, DFG has jurisdiction over the conservation, protection, and management of fish, wildlife, native plants, and habitat necessary for biologically sustainable populations of those species. The purpose of DFG's comments is to provide guidance to the SFPUC to ensure that, if the Project under the Water System Improvement Program (WSIP) is implemented, biological resources are protected. Like the draft EIR, DFG has organized comments beginning with the WSIP and proceeding with comments by each respective section.

Project Description

The proposed Project would consist of the following components:

Tesla Treatment Facility (Tesla Portal Site)

- A 14,000-square-foot Chemical Process Building, 32 feet in height containing three 16,000-gallon sodium hypochlorite tanks, two 10,000-gallon fluoride tanks and two outdoor 12,500-gallon carbon dioxide (CO_2) tanks.

- A 3,500-square-foot Office/Control Building, 12 feet in height containing offices, control room, process room, laboratory, restrooms, lockers, shower, and a multipurpose room.

- A 20,000-square-foot UV Building, 32 feet in height containing 12 UV reactors (10 active and two standby) each with UV lamp arrays and various sensors on a floor recessed approximately 14 feet below-grade, below-grade piping vaults and two 3,000-gallon food-grade acid tanks.

- Other proposed improvements at the Tesla Portal site include a 90,000-gallon containment basin lined with rip rap to capture released water for grit removal and periodic maintenance (three times per month), two valve vaults to direct adequate flow, as required, two valve houses, and other infrastructure including a microwave tower up to 100 feet in height.

Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)

- Two UV reactors (one active and one standby) installed within the existing Chlorination Facility building.

- A 360-square-foot prefabricated structure 10 feet in height within the fenced area atop Thomas Shaft.

- A 2,500-gallon percolation water tank for processed water.

The proposed project would improve already existing uses (i.e., water treatment) at the two sites. The Lawrence Livermore Water Quality Improvements are being designed for a 0.165 million gallons per day (mgd) capacity. The proposed project would allow Lawrence Livermore National Laboratory (LLNL) to take up to 0.165 mgd of their annual average demand of 0.8 mgd from Thomas Shaft, and continue to receive the remainder of the water from Mocho Shaft, an SFPUC facility located downstream of the Thomas Shaft site. The amount of water supplied to LLNL would be consistent with the preexisting contract between the two parties.

Project Objectives

The objectives of the proposed Project consist of the following:

Tesla Treatment Facility (Tesla Portal Site)

- Replace existing water treatment facilities that are not currently seismically safe with new facilities that are designed to meet current seismic, safety/fire, and building code standards.

- Construct new water treatment facilities to meet U. S. Environmental Protection Agency (U. S. EPA) requirements for *Cryptosporidium* reduction/inactivation in drinking water, as required under the U. S. EPA's Long Term-2 Enhanced Surface Water Treatment Rule (LT2ESWTR).

- Improve current water quality management capabilities such as pH control.

Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)

- Construct new water treatment facilities to meet U.S. EPA requirements under the Surface Water Treatment Rule for the reduction/inactivation of *Giardia*, as well as assist in meeting LT2ESWTR *Cryptosporidium* requirements to enable delivery of potable water to LLNL from the Thomas Shaft of the Coast Range Tunnel.

- Continue to provide back-up chlorination capabilities.

Comments on Executive Summary

WSIP Water Supply Option, Pg. 1-6: Through the WSIP, the SFPUC proposes a water supply option to address the water supply level of service objective of meeting a projected 35 mgd increase in customer purchase requests by 2030, and to provide drought-year delivery with a maximum systemwide rationing of 20 percent. This strategy includes maximizing the use of local watershed supplies, increasing diversions from the Tuolumne River under existing water rights, and development of new local resources, including additional conservation, water recycling, and groundwater supply programs in San Francisco. This combination of water supply sources is expected to fully meet customer purchase requests during non-drought years through 2030. [01]

On October 7, 2007, DFG provided comments to the draft Program Environmental Impact Report (PEIR) for the WSIP proposed by the SFPUC which included comments to the proposed water supply option. DFG reiterates the following comments as well as others in the PEIR as previously stated and provides new comments with respect to current information.

Lower Tuolumne River (Below New Don Pedro)

The PEIR states that the implementation of WSIP would have no impact on the current minimum instream flow requirement set by the Federal Energy Regulatory Commission (FERC) in the 1996 Fishery Settlement Agreement. DFG is concerned that the current FERC required flow regime (i.e., PEIR's CEQA baseline conditions) may not be sufficient to prevent salmon populations in the Tuolumne River from declining. In fact, we have evidence demonstrating that adult Tuolumne River fall-run Chinook salmon *(Oncorhynchus tshawytscha)* produced at a given spring flow has declined by about 50% (mean of 6,805 [02]

recruits) since the FERC Settlement Agreement was implemented in 1996. The decline is statistically significant based on an F-test comparison of two flow recruitment regression models: one based on the period from 1980 to 1990 and the other based on the period from 1998 to 2003. We believe that, as proposed, WSIP would make these conditions worse for Tuolumne River salmonids, thus exacerbating the current decline of this population. To address this concern, DFG wrote a letter dated August 1, 2007 to Secretary Kathleen Bose of the FERC and requested them to direct the Modesto Irrigation District and Turlock Irrigation District to provide higher magnitude and greater duration instream flows during the spring period of each year in order to assure acceptable salmon smolt survival and assure that the now critically-impaired salmon populations will remain intact until a new license is considered for Project 2299 in 2014. In this letter, DFG presents evidence, which is summarized below, that demonstrates strong correlations between this observed population decline and the conditions of reduced spring flow and elevated spring water temperature, as directly caused by the operations of Project 2299.

The CEQA environmental baseline conditions in the Lower Tuolumne River are essentially driven by the operations of Project 2299 which, for reasons we identify below, are creating conditions that are not suitable for the anadromous fisheries in the Tuolumne River. Although we recognize that the City and County of San Francisco are not the licensees for Project 2299, it is irrefutable that the actions of the SFPUC on the Tuolumne River at Early Intake, Cherry Valley Dam, and Hetch Hetchy and Lake Eleanor reservoirs influence the timing, duration, and magnitude of water releases from the New Don Pedro Dam. Increased diversion of waters from a river system which currently lacks sufficient flow to support sustainable anadromous fisheries including Federally Threatened Central Valley steelhead (*Oncorhynchus mykiss iridieus*) should be considered a significant cumulative impact (see Zimmerman et al. 2008). Although the proposed increase in diversion in itself may (arguably) not be deemed significant, when viewed in conjunction with Project 2299, existing SFPUC diversions, and other diversions from the Tuolumne River, the effects are cumulatively considerable [see CCR Title 14, Section 15065(a)(3)]. In this context, *we believe the proposed project has the potential to cause anadromous fish populations to drop below self-sustaining levels and further reduce the number and restrict range of Federally Threatened Central Valley steelhead* – thereby requiring a finding of significant effect [CCR Title 14, Section 15065 (a)(1)]. Therefore, we respectfully request the SFPUC use alternative water sources other than the Tuolumne River system to meet purchase requests in 2030 and drought year demands, at least until Project 2299 can properly address the inadequacies in the current flow regime for the purpose of creating, enhancing and supporting a sustainable anadromous fishery in the Lower Tuolumne River. [02] cont.

Documented Tuolumne River Salmon Population Decline

Strong evidence exists that the Tuolumne River fall-run Chinook salmon population has declined severely. Historically, this fall run was documented (U. S. Fish and Wildlife Service 1940) to annually exceed 72,000 escaping (i.e., spawning) adults. This number became reduced severely, coincidentally with, and in part caused by, water diversions and dams which were developed and operated on the Tuolumne River. Immediately prior to the operation of the New Don Pedro Project, fall-run Chinook salmon numbers annually reached 20,000 to 25,000 escaping adults, but unfortunately the instream flow and other

fishery protection measures included in the original Project 2299 license were inadequate to stem the continuing decline of salmon. By the time of the 1996 Fisheries Settlement Agreement, salmon numbers had progressively declined to less than 1,000 adults annually. This decline, both overall and when dissected into various lifestage survival components, very strongly correlates with Tuolumne River flow inadequacy during critical salmon life-stages.

In 1997, a record high water year produced substantial project spill, essentially rendering moot the fishery effects of Project 2299 water operations, as well as the effects of some of the out-of-tributary influences on juvenile salmon survival during that year. Absent those controlling influences, the salmon experienced much greater juvenile survival and downstream migration success. Accordingly, in 2000, when most of these fish returned to the Tuolumne River as adults, we documented runs well in excess of 18,000 individuals. Unfortunately, that benefit was short-lived. Since 2000, and after normal Project 2299 operations resumed, the Tuolumne River salmon escapements have again sharply declined. As of 2006, the Tuolumne River escapement population had dwindled to about 600 returning adults. This represents an order-of-magnitude salmon population reduction during the time when the Fishery Settlement Agreement flows and other "protective conditions" under that agreement were in full effect.

Subsequently, since comments were made to the PEIR in October 2007, in a report titled "Lower Tuolumne River Spawning Report, Spawning Survey Summary Update, March 2008" (Ford & Kirihara 2008), run size estimate for Tuolumne River Chinook for 2007 was 211 fish. The current run size of 211 fish with the declines experienced over recent years clearly show the Tuolumne River Chinook to be at *high risk of extinction*, (Lindley 2007). Additionally, USFWS issued a preliminary analysis which indicates that the Tuolumne River fall-run Chinook salmon population of naturally produced fish "is at a high risk of extinction because the instream flow releases are too low" (Mesick 2008). The report finds that "the Tuolumne River fall-run Chinook salmon population is at a high risk of extinction because the population of naturally produced fish was probably less than 83 for three consecutive years (2005 to 2007), there was precipitous decline, and the fall 2007 escapement was a catastrophe considering the spring 2005 wet year conditions." It identifies the Project's control of instream flow to be a significant limiting factor affecting natural salmon production: "The number of naturally produced adult salmon that return to the Tuolumne River is primarily a response of the juvenile salmon to the flows released at La Grange Dam during the winter and spring…" [02] cont.

In a request for rehearing letter written by DFG on May 5, 2008 to FERC, DFG wrote that neither ocean harvest, ocean conditions, nor Delta exports, even though they are in fact minor sources of mortality, are strong controlling factors in the abundance, health and vitality of the Tuolumne River adult salmon population. Annual adult salmon escapement abundance in the Tuolumne River began its sharp decline well before the poor ocean condition phenomena experienced in summer of 2007 (Figure 9, Page 16, Marston 2008). Additionally, a new analysis of the relationship between Delta smolt survival and Delta exports, and San Joaquin River inflow [i.e. Tuolumne River contributions along with other tributary flows (Newman 2008)] suggest that the Tuolumne River adult salmon population is

primarily affected and controlled by in-tributary limiting factors, rather than oceanic or other downstream controlling features.

As further described in the DFG letter written on May 5, 2008 to FERC, the primary factors controlling the salmon population to the Tuolumne River are occurring within the reach of the River which is directly operated in association with Project 2299. Districts have asserted that other downstream factors within the San Joaquin River and Delta are principally responsible for the observed salmon population declines. However, since Tuolumne River flow contributions from the Project requirements are important in determining the fate of salmon and other species (e.g., Delta smelt, longfin smelt, steelhead), in the Delta this, too, is a direct effect of Project operations. We have observed a very dramatic decline in Tuolumne River salmon adult escapement between 2000 and 2007, while the Fishery Settlement Agreement flow regimes and other protective features have been in place. The strong relationship between this observed population decline and the conditions of reduced spring flow and elevated spring water temperature indicated needed changes in the operations of Project 2299. Our analysis, only a part of which is provided above, shows fairly comprehensively that out-of-tributary limiting factors are indeed in play, yet are not the most important determinants of Tuolumne River salmon production, by at least an order-of-magnitude. [02] cont.

Alternatives to the WSIP

Accordingly, the WSIP draft PEIR identified the Modified WSIP Alternative as the environmentally superior alternative. This alternative implements all of the proposed WSIP projects, but would modify proposed system operations to minimize environmental effects. Modified proposed system operations to be considered as environmentally minimal must not include increased diversions from the Tuolumne River. Since there is strong evidence the Tuolumne River as managed, for the reasons discussed above and others, lacks sufficient water flows to keep in good condition anadromous salmonids, DFG does not agree with increased diversions from the Tuolumne River. Diversions of even 3-mgd of water from the Tuolumne River would be cumulatively considerable [see CCR Title 14, Section 15065(a)(3)] and put Chinook salmon at *high risk of extinction* in that watershed. Consequently, we continue to respectfully request SFPUC to use alternative water sources other than the Tuolumne River system to meet purchase requests in 2030 and drought year demands, at least until Project 2299 can properly address the inadequacies in the current flow regime for the purpose of creating, enhancing and supporting a sustainable anadromous fishery in the lower Tuolumne River. [03]

DFG encourages SFPUC continue aggressive conservation and water recycling. Furthermore, year-round desalination at Oceanside to provide 25-mgd customer purchase requests through 2030 could be a good alternative for protecting salmonids of the Tuolumne River. With the implementation of alternative energy sources and proper brine disposal, such as dilute diffusion, the desalination alternative has the potential to be an environmentally superior alternative.

Comments on Biological Resources

California Annual Grassland, Pg. 4.6-1: California annual grassland is the predominant natural community at the Project sites. At the Tesla Portal site, there are approximately 42 acres of California annual grassland, and about 25.6 acres of annual grassland at the Thomas Shaft site. The proposed Project would result in the permanent loss of approximately 3.2 acres of California annual grassland at the Tesla Portal site. Permanent loss of California annual grasslands would contribute incrementally to the statewide loss of this type of habitat. As such, the impact of permanent loss of California annual grasslands from the proposed Project combined with the permanent loss of California annual grasslands of other projects identified in Table 4.15-a would be potentially significant (pgs. 4.15-13 and 4.15-14). Therefore, loss of California annual grassland at the Tesla site would contribute to a "cumulatively considerable" impact and substantially degrade the quality of the environment as stated in Section 15065 of the CEQA guidelines. Mitigation Measure 4.6-1a indicates participation in the San Joaquin Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) which includes compensation for the permanent loss of 0.308-acre of habitat values of artificial wetland, the temporary loss of <0.001-acre of ephemeral drainage, the temporary loss and permanent conversion of natural lands and incidental take authorization for special-status species. Participation in the SJMSCP should include, but not be limited to, 3.2 acres of permanent conversion of California annual grassland. [04]

Special-Status Plant Species, Pg. 4.6-6: One special-status plant species, Mt. Diablo cottonweed, was observed along the access road leading to the Thomas Shaft site, but is not located within the Project footprint or construction staging area (Weiss Associates, 2003). During construction, the access road to the Thomas Shaft site should not be modified in any way which could impact Mt. Diablo cottonweed. [05]

According to the May and Associates technical report on page 55 in the table titled "Plants Observed," both the Thomas Shaft and Tesla sites have known occurrences of *Amsinckia* spp. It is important a distinction is made which *Amsinckia* spp. is present since *Amsinckia grandiflora* is Federally- and State-listed as endangered, and has CNPS status 1B. *Amsinckia lunaris* also has CNPS status 1B. Until this distinction has been made, construction activities should be restricted. [06]

Impacts on sensitive habitats, common habitats, and heritage trees (Tesla Portal: PSM; Thomas Shaft: LS, pg. 4.6-23): Temporary impacts resulting from construction staging and other construction-related activities at the Tesla Portal Project site would result in impacts to 11.716 acres of California annual grasslands, <0.001-acre of ephemeral drainage, and 0.846 acre of ruderal/disturbed habitat. Temporary impacts to California annual grasslands and aquatic habitat would contribute to the degradation of natural habitat in the region and could result in the potential permanent loss of habitat. Mitigation Measures 4.6-1a, 4.6-1b and 4.6-2 (participation in the SJMSCP, implement Best Management Practices and returning the site to pre-project conditions) would reduce potential temporary construction impacts to less than significant. [07]

Since prior to the commencement of construction activities, the SFPUC will coordinate with the Joint Powers Authority/Technical Advisory Committee and pay necessary fees to fund offsite compensation under the terms of the SJMSCP, any temporary impacts that could result in the potential permanent loss of habitat should be considered as a permanent impacts. [07] cont.

Comments on Special Status Wildlife Species [08]

Implement Incidental Take Minimization Measures for San Joaquin Kit Fox, Pg. 5-6: A qualified biologist shall conduct preconstruction surveys 14 to 30 calendar days prior to commencement of ground disturbance. These surveys should be conducted no later than two weeks prior to commencement of ground disturbance.

Preconstruction surveys for the San Joaquin kit fox should adhere to the U. S. Fish and Wildlife Service's (USFWS) San Joaquin Kit Fox Survey Protocol for the Northern Range. Accordingly, DFG recognizes properly qualified biologists conducting San Joaquin kit fox surveys as described by the USFWS must have demonstrable experience in kit fox biology, identification and survey techniques. [09]

Furthermore, DFG as described by the USFWS Standardized Recommendations for Protection of the San Joaquin Kit Fox Prior to or During Ground Disturbance (1999), does not consider water storage or conveyance facilities that promote urban growth or agriculture small projects. Recommendations for take minimization measures for San Joaquin kit fox should follow the above referenced document under the section "other projects."

Determine Burrowing Owl Presence

Breeding Season Surveys

The California Burrowing Owl Consortium (Consortium) survey protocol specifies a multi-phase approach, which is recommended in order to adequately evaluate burrowing owl use of an area and to inform the CEQA process. Phase 1 of the protocol begins with a habitat assessment that recognizes that burrows are the essential component of burrowing owl habitat and that burrowing owls may use man-made structures as burrows (see Page 1 of Consortium guidelines). If suitable habitat [appropriate vegetation and burrow(s) or burrow surrogate(s)] is present, then a Phase 2 intensive burrow survey is necessary even if owl sign is not present during the habitat assessment phase. Owl signs include molted feathers, cast pellets, prey remains, egg shell fragments, or excrement at or near burrow entrance or perch site. During the intensive burrow survey phase, burrow concentration areas should be mapped. Phase 3 of the protocol requires four survey visits whether or not owl sign is observed during Phase 2. DFG recommends that the Consortium survey protocol for breeding season surveys be adhered to [4 survey visits spread evenly (roughly every three weeks) during the peak of the breeding season, from April 15 to July 15] until enough information is available to warrant their revision or until new detailed protocols are developed as part the Conservation Strategy. The habitat assessment, intensive burrow surveys and burrowing owl surveys should include the area within 150 meters of the Project boundaries (approximately 500 feet). [10]

Non-Breeding Season Surveys (Including Winter)

Surveys during the non-breeding season (September 1 to January 31) are recommended by DFG but are not generally required because burrowing owls are much more difficult to detect during the non-breeding season, and the number or type of surveys that would be needed to detect presence then has not been studied or quantified. Owls detected during non-breeding season surveys may be year-round residents or their young from the previous nesting season, pre-breeding territorial adults, winter residents, dispersing juveniles, migrants, or new colonizers. Negative results during any non-breeding season surveys are not conclusive proof that owls do not use the site. Because of this complication, DFG recommends breeding season surveys as the first step, but project applicants should consult with DFG if burrowing owls have been documented on the Project site during the non-breeding season.

Avoid Impacts (destruction, disturbance) to Individual Owls

Pre-Construction Surveys for Owl Presence

Pre-construction surveys (usually initiated during the non-breeding season) are necessary for assessing owl presence at a site within a short time period before site modification is scheduled to begin. Pre-construction surveys are supplemental to the existing breeding season survey protocol (four survey visits spread evenly during the peak of the breeding season, from April 15 to July 15), and should not be used in place of it without consulting with DFG in advance. The pre-construction surveys are intended to document if colonizing owls have recently moved onto the site, or if burrow locations of resident owls have changed, or if young of the year are still present and have not yet fledged or dispersed. Because any one or all of these events may have occurred on site since the breeding season (protocol) surveys were completed, it is important to also complete the pre-construction surveys in order to avoid direct take of owls or their nests and to design proper minimization and mitigation measures (e.g., document number and reproductive status of resident owls and location of satellite burrows, establish buffer zones and equipment/personnel travel routes and work/storage areas, unequivocally evict owls and ground squirrels from burrows). [10] cont.

Initial pre-construction surveys should be conducted outside of the owl breeding season (from February 1 to August 31) but as close as possible to the date that ground-disturbing activities will begin, to avoid the problem of waiting until March or April when the Project would be delayed if owls are detected. Generally, initial pre-construction surveys should be conducted no more than 30 days prior to ground-disturbing activities (i.e., disking, clearing, grubbing, grading). The time lapse between surveys and site disturbance should be as short as possible and will be determined by DFG based on specific project conditions but generally should not exceed seven days. Additional surveys are necessary when the initial disturbance is followed by periods of inactivity or the development is phased spatially and/or temporally over the Project area.

The number of pre-construction surveys necessary to accurately detect current owl presence and owl locations will be driven by a number of interacting criteria such as: 1) the time period that has elapsed since the last breeding survey was completed; 2) height and density of vegetation that may obscure owl presence; 3) topographical conditions that may

obscure owl presence; 4) time of year (e.g., in the winter owls are more cryptic and spend more time in their burrows); 5) time of day and weather conditions when surveys are conducted; 6) long-term history of owl use at the site; 7) size of the parcel and degree of coverage by walking or by intensive observations via spotting scope, and 8) tolerance of owls to human presence. Generally, at a minimum, four survey visits on at least four separate days will be necessary, especially given the cryptic nature of this species during the non-breeding season.

Biologists conducting pre-construction surveys should expend enough effort, based on the above criteria, to assure with a high degree of certainty that take of owls will not occur once site modification and grading activities begin. The full extent of pre-construction survey effort must be described and mapped in detail (e.g., dates, time periods, area(s) covered, and methods employed) in a biological report. Current vegetation and topographical conditions and their corresponding effect on visibility should also be described. The report should be submitted to DFG for review.

DFG's concurrence with the pre-construction survey results will depend on the level of detail that is provided in the Consultant's biological report that summarizes the methods, results, and level of survey effort. DFG has a responsibility to give input regarding measures that would result in avoiding take and minimizing unavoidable impacts to owls.

[10] cont.

Take Avoidance

Avoidance of take of individual burrowing owls and their nests is currently mandated under Fish and Game Code sections 86, 3503, 3503.5 and 3513.

Burrows are an essential ecological requisite for burrowing owls throughout the year. Loss of nest burrows, satellite burrows, breeding concentrations, foraging habitat, dispersal and migration habitat, wintering habitat, habitat linkages and stepping stones, including habitat supporting host burrowers, and other essential habitat attributes, can individually or collectively have significant impacts on burrowing owls. DFG will work with Project proponents and lead agencies to develop compensatory mitigation for impacts to burrowing owls.

Conduct Pre-Construction Surveys for Swainson's Hawk, Pg. 5-8: A distance of two times the dripline of the tree is arbitrary and in the event any occupied nests are found, DFG will help determine appropriate actions based on scientific recommendations for construction activities. These measures may include waiting for the birds to fledge and forage on their own prior to construction or having a biological monitor on site to determine an appropriate buffer by monitoring any changes in behavior. If any Swainson's hawks are found nesting in the area, DFG should be notified to determine appropriate actions.

[11]

Implement Incidental Take Minimization Measures for White-Tailed Kite, Pg. 5-8: The white-tailed kite is a Fully-Protected species under Fish and Game Code Section 3511. Fully-Protected species may not be taken or possessed at any time and no licenses or permits may be issued for their take except for collecting these species for necessary scientific research. Therefore, the avoidance measures must prevent the take of these

[12]

species. If the species is found nesting, a setback from nesting areas shall be established far enough away to prevent any impacts. The buffer shall be maintained during the nesting season for the period encompassing nest building and continue until fledglings leave nests. If any white-tailed kites are found nesting, DFG should be notified to determine or confirm an appropriate buffer zone. [12] cont.

Implement Incidental Take Minimization Measures for California Horned Lark and Northern Harrier, Pg. 5-9: If species are found, a setback of 500 feet from nesting areas shall be established and maintained for the period encompassing nest building and continuing until fledglings leave nests, unless other measures are agreed to by DFG, or offsite compensation shall be provided. If any bird nests are found, DFG should be notified to determine or confirm the appropriate buffer zone for the species. [13]

Conduct Pre-Construction Surveys for Golden Eagle, Pg. 5-9: Golden eagles are Fully-Protected under Fish and Game Code Section 3511. Fully-Protected species may not be taken or possessed at any time and no licenses or permits may be issued for their take except for collecting these species for necessary scientific research. Therefore, the avoidance measures must prevent the take of these species. If the species is found nesting, a setback from nesting areas shall be established far enough away to prevent any impacts. The buffer shall be maintained during the nesting season for the period encompassing nest building and continuing until fledglings leave nests. If any nests are discovered, DFG should be notified to determine appropriate actions. [14]

Conduct Pre-Construction Surveys for Ferruginous Hawk and Prairie Falcon, Pg. 5-10: If species are found, a setback of 500 feet from nesting areas shall be established and maintained for the period encompassing nest building and continuing until fledglings leave nests, unless other measures are agreed to by DFG. If any bird nests are found, DFG should be notified to determine or confirm the appropriate buffer zone for the species. [15]

We appreciate your consideration of our comments. If you have any questions, please contact Mr. Wes Stokes, Environmental Scientist, at (707) 944-5571 or wstokes@dfg.ca.gov; or Mr. Greg Martinelli, Water Conservation Supervisor, at (707) 944-5570.

Sincerely,

Charles Armor

10.2 Response to Comments from the California Department of Fish and Game (S-CDFG)

[S-CDFG-01]

The commenter provides comments on the Water System Improvement Program (WSIP), which were reviewed and considered as part of the certification process for the Program EIR (PEIR) on the WSIP. The commenter focuses on the impacts of the originally proposed WSIP. On October 30, 2008, the San Francisco Planning Commission certified the Final PEIR in its Motion No. 17734 and the SFPUC adopted the WSIP (known as the "Phased WSIP") in its Resolution No. 08-0200. The Phased WSIP is a variant on the originally proposed WSIP, and defers the decision to deliver more water to the SFPUC's customers until 2018. The Phased WSIP involves *full implementation of all proposed WSIP facility improvement projects* to ensure that the public health, seismic safety and delivery reliability goals are achieved as soon as possible *and phased implementation of a water supply program to meet projected water purchases through 2030*. Under the Phased WSIP, the SFPUC established an interim mid-term planning horizon – 2018. The SFPUC made a decision about providing water supply to the water customers through 2018 only, and deferred a decision regarding long-term water supply after 2018 and through 2030 until it undertakes further water supply planning and demand analysis. All non-water supply–related goals and system performance objectives identified for the original WSIP would be achieved under the Phased WSIP and all individual WSIP facility improvement projects proposed in the original WSIP would be constructed. PEIR Chapter 13 provides a description and analysis of the Phased WSIP and is included in this EIR as Appendix B.

Description of the Phased WSIP

The Phased WSIP includes the following key program elements:

- Full implementation of all of the 17 proposed WSIP facility improvement projects described in the PEIR, including the Tesla Treatment Facility and the Lawrence Livermore Water Quality Improvements analyzed in this EIR.[1]

- Water supply delivery to regional water system customers through 2018 only of 265 million gallons per day (mgd) average annual target delivery originating from the Tuolumne, Alameda and Peninsula watersheds. This includes 184 mgd for the wholesale customers (including 9 mgd for the cities of San Jose and Santa Clara), and 81 mgd for the retail customers.

- Development of 20 mgd of conservation, recycled water and groundwater within the service area (10 mgd retail; 10 mgd wholesale).

- Dry year transfer from Modesto Irrigation District (MID) and/or Turlock Irrigation District (TID) of about 2 mgd coupled with the Westside Groundwater Basin conjunctive

[1] The Tesla Treatment Facility and the Lawrence Livermore Water Quality Improvements are listed as three separate projects in the WSIP PEIR: the Tesla Portal Disinfection Facility, Advanced Disinfection, and the Lawrence Livermore Supply Improvements.

use project to meet the drought year goal of limiting rationing to no more than 20 percent on a systemwide basis.

- Re-evaluation of 2030 demand projections, potential regional water system purchase requests, and water supply options by 2018 and a separate SFPUC decision in 2018 regarding regional water system water deliveries after 2018.

- Financial incentives to limit water sales to an annual average of 265 mgd from the watersheds.

The Phased WSIP would not provide water supply to meet 300 mgd average annual water sales in 2030 as proposed under the original WSIP. Rather, the SFPUC would limit deliveries to no more than an annual average of 265 mgd from the watersheds through 2018, and the SFPUC and wholesale customers would collectively develop 20 mgd in conservation, recycled water, and groundwater to meet or offset the projected regional water system purchase request of 285 mgd in 2018. This 20 mgd of conservation, recycled water, and groundwater includes development of 10 mgd of conservation, recycled water, and groundwater in San Francisco as proposed under the WSIP and 10 mgd of conservation, recycled water, and groundwater developed by the wholesale customers, which is in addition to 15 mgd of conservation, recycled water, and groundwater already assumed by the wholesale customers in preparing their regional water system purchase requests.

There is no change between the WSIP and the Phased WSIP in the average annual water delivery proposed for the SFPUC's retail customers; the current average annual retail customer demand is approximately 91 mgd and this same amount would be provided to the retail customers through 2018, although 10 mgd of this amount would be provided through conservation, recycled water, and groundwater developed in San Francisco. While the WSIP proposed to provide the full 2030 projected wholesale customer average annual purchase requests of 209 mgd, the Phased WSIP instead is designed to meet a projected 2018 wholesale customer average annual purchase request of 194 mgd in 2018, although 10 mgd of this amount would be provided through conservation, recycled water, and groundwater projects.

Under the Phased WSIP, the SFPUC also would implement the delivery and drought reliability elements of the WSIP, including the Westside Basin Conjunctive Use Project and proposed dry-year transfers from the MID and the TID, which would increase average annual diversions from the Tuolumne River by about 2 mgd over existing conditions.

Before 2018, the SFPUC would engage in a new planning process to re-evaluate water system demands and water supply options. As part of the process, San Francisco would conduct additional environmental studies and CEQA review as appropriate to address the SFPUC's recommendation regarding water supply and proposed water system deliveries after 2018. The SFPUC would review and consider approval of the terms of any new master Water Sales Agreement that would take effect after 2018.

The SFPUC will deliver to customers up to 265 mgd from the SFPUC watersheds on an average annual basis. While average annual deliveries from the SFPUC watersheds would be limited to 265 mgd such that there would be no increase in diversions from the Tuolumne River to serve additional demand, there would be a small increase in average annual Tuolumne River diversions of about 2 mgd over existing conditions to meet the delivery and drought reliability elements through 2018. As part of adoption of the Phased WSIP, the SFPUC will implement the mitigation measures identified for the Phased WSIP in the Final PEIR, including measures addressing interim impacts from potential increases in deliveries from the SFPUC watersheds over the total average annual of 265 mgd in the event that conservation, recycled water, and groundwater projects are not completed prior to the increase in customers' demand.

The SFPUC must maintain water deliveries to all its customers for the protection of public health and safety. Therefore, the SFPUC will work with its customers to develop financial incentives to limit water sales to an average annual amount of 265 mgd from the watersheds through 2018. With the projected 20 mgd of conservation, recycled water, and groundwater projects, the system would meet average daily demand of 285 mgd in 2018.

Environmental Analysis of the Phased WSIP

The Phased WSIP would have the same potential impacts associated with proposed facility construction and operation as the WSIP. The 17 facility improvement projects proposed under the WSIP and analyzed in the PEIR would also be implemented under the Phased WSIP to meet the intent of the water quality, seismic reliability, delivery reliability, and water supply goals of the WSIP.

The Phased WSIP would have potential impacts associated with its proposed water supply program similar to those described in the PEIR for the alternatives where the wholesale customer purchase requests for 2030 would not be provided by the regional water system. Under those alternatives, the PEIR assumed that the wholesale customers might pursue other types of projects to either reduce demand and/or to supplement the surface water supplies delivered by the regional water system from the SFPUC watersheds. The potential facility and operations impacts associated with such projects are discussed in the analysis for the alternatives, including the No Program Alternative, the No Purchase Request Increase Alternative, and the Aggressive Conservation/Water Recycling and Local Groundwater Alternative.

Similar to the Modified WSIP Alternative and the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, the Phased WSIP, which envisions developing additional local conservation, recycled water, and groundwater projects, could result in construction and operation of additional recycled water and groundwater facilities in the wholesale customer service areas; thus, collective impacts in the Bay Division and Peninsula Regions and associated cumulative effects would occur. The types of potential impacts associated with implementation of the local recycled water and groundwater projects are summarized in PEIR Table 13.9 and Section 13.4 (see Appendix B of this EIR) and generally relate to construction

of new infrastructure, water quality, and groundwater resources, and operational uses of energy and long-term air quality emissions.

The water supply impacts of the Phased WSIP would be similar to those analyzed in Chapter 9 of the WSIP PEIR for the No Purchase Request Increase Alternative, and overall the impacts of the Phased WSIP Variant through 2018 would be less than the water supply impacts of the WSIP (see Appendix B of this EIR). With a few exceptions, the water supply impacts identified as potentially significant and mitigable for the proposed WSIP remain potentially significant and mitigable for the Phased WSIP. Two potential impacts on the lower Tuolumne River were determined to be less than significant as long as the SFPUC does not increase deliveries to customers above 265 mgd from the watersheds: WSIP Impact 5.3.6-4, potential effects on fishery resources along the Tuolumne River below La Grange Dam; and WSIP Impact 5.3.7-6, potential impacts on terrestrial biological resources along the Tuolumne River below La Grange Dam (see Appendix B of this EIR). Although the Phased WSIP is designed to keep deliveries from exceeding an annual average level of about 265 mgd, in the event the SFPUC must deliver more than 265 mgd to its customers from the watersheds, the SFPUC shall implement the mitigation measures associated with these potential impacts in proportion to the extent of the exceedance. In implementing the Phased WSIP, the need could arise to temporarily increase deliveries from the Tuolumne River and local watersheds over the 265 mgd average annual target levels to meet customer water delivery needs in the near term, because of public health and safety considerations and because it might not be possible to implement all of the local conservation, recycling, and groundwater projects and actions in time to meet increasing customer demands. Although avoidance of these potential impacts on the lower Tuolumne River is not ensured, the magnitude, frequency, and duration of the impacts are likely to be less than the originally proposed WSIP. The impact analysis for the Phased WSIP recognized that, between now and 2018, deliveries from the Tuolumne River and local watersheds might increase above the 265 mgd average annual level (to a possible 275 mgd average annual) for up to a few years. By 2018, and perhaps well before, it is expected that local projects would provide sufficient local supply and conservation to bring SFPUC watershed deliveries back down to current levels, an annual average of 265 mgd.

Under the Phased WSIP, the SFPUC would monitor sales to ensure that sales delivered from the SFPUC watersheds are limited to an average annual of 265 mgd through 2018. The SFPUC would measure and review average annual sales at the close of each fiscal year. WSIP Mitigation Measures 5.3.6-4a or 5.3.6-4b, as well as WSIP Mitigation Measure 5.3.7-6 (see Appendix B of this EIR), will be implemented when the average annual sales from the watersheds exceed 265 mgd. The SFPUC would continue to implement the necessary measure(s) until the average annual SFPUC watershed deliveries are 265 mgd or less. Implementation of WSIP Measure 5.3.6-4a is the preferred mitigation approach, and for the Phased WSIP, the amount of conserved water required to reduce the potential impact to a less-than-significant level would be proportional to the amount of increased diversions from the Tuolumne River contributing to exceeding the 265 mgd deliveries restriction.

Four potential impacts in the Pilarcitos watershed were determined to be potentially significant and mitigable for the originally proposed WSIP, but are considered less than significant for the Phased WSIP through 2018: Surface Water Quality Impact 5.5.3-2, effects on water quality in Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam; Fisheries Impacts 5.5.5-4, effects on fishery resources in Pilarcitos Reservoir, and 5.5.5-5, potential effects on fishery resources along Pilarcitos Creek below Pilarcitos Reservoir and below Stone Dam; and, Terrestrial Biology Impact 5.5.6-4, potential impacts on biological resources in Pilarcitos Reservoir. With the Phased WSIP, operations for Pilarcitos Reservoir and releases to Pilarcitos Creek will be similar to existing conditions, resulting in a less-than-significant impact. Thus no mitigation is required. (WSIP Draft PEIR pp. 5.5.3-5 through 5.5.3-7, 5.5.6-17 through 5.5.6-22, 5.5.5-7, 13-39, 13-44, and 16-80 to 16-82. See Appendix B of this EIR.)

Please refer to Chapter 3, Staff-Initiated Text Changes, of this Comments and Responses for revisions to Chapters 1, 2, 3, 4.1, 6, 7, 9, and Appendix B of the SJRWQIP Draft EIR related to the Phased WSIP.

[S-CDFG-02]

The commenter states that the WSIP could cause anadromous fish populations of the Tuolumne River to drop below self-sustaining levels and that evidence supports an existing decline in Chinook salmon populations. As discussed below, the WSIP PEIR concluded that long-term WSIP-induced flow changes in the Tuolumne River below La Grange Dam could have a potential significant adverse effect on anadromous fish in that reach of river if left unmitigated. The analysis in the WSIP PEIR indicates that implementation of WSIP Mitigation Measures 5.3.6-4a and 5.3.6-4b would reduce these potential impacts to a less-than-significant level (WSIP PEIR pp. 6-48 and 6-49; see Appendix B of this EIR).

The commenter expressed the preference that the SFPUC's WSIP obtain additional water from sources other than the Tuolumne River. It should be noted that the WSIP PEIR analyzed potential impacts based on increased Tuolumne River diversions under 2030 purchase request conditions. Under the Phased WSIP, the SFPUC established an interim mid-term planning horizon – 2018. The SFPUC made a decision about providing water supply to the water customers through 2018 only, and deferred a decision regarding long-term water supply after 2018 and through 2030 until it undertakes further water supply planning and demand analysis. Thus, the Phased WSIP would include lower purchase requests (i.e., water demand), smaller increases in diversions, and therefore less severe impacts would be expected under the Phased WSIP. Please refer to the discussion above under the response to comment S-CDFG-01 for a description of the Phased WSIP and the anticipated environmental impacts.

The WSIP PEIR provides information on Chinook salmon populations in the Tuolumne River (WSIP PEIR pp. 5.3.6-13 to 5.3.6-17; see Appendix B of this EIR). Table 5.3.6-2 of the WSIP PEIR shows the results of spawning surveys for the period 1971 to 2004, which show a declining trend in Chinook salmon production.

The information on Chinook salmon provided in the WSIP PEIR was sufficient to reach the conclusion that the WSIP could have a potentially significant adverse impact on salmonids in the Tuolumne River below La Grange Dam. As stated in the WSIP PEIR (pp. 5.3.6-28 to 5.3.6-32; see Appendix B of this EIR), overall flow reductions coupled with the projected infrequent water temperature increases that could result from the WSIP would have a potentially adverse impact on habitat conditions for juvenile salmonids. *The Habitat Restoration Plan for the Lower Tuolumne River Corridor* (McBain and Trush, 2000) establishes goals for fishery habitat restoration, and the National Marine Fisheries Service (NMFS) and others have identified goals for fishery enhancement in this reach of the river. The WSIP's small but incremental contribution to adverse effects on the lower river would make planned restoration of habitat and fishery resources more difficult. Thus, the WSIP PEIR reflects the view that the WSIP has the potential to cause a significant adverse effect on anadromous fish in the Tuolumne River below La Grange Dam.

The following supplemental information was provided as part of the Final WSIP PEIR.

The San Joaquin River and its major tributaries historically supported large populations of both spring-run and fall-run Chinook salmon. During the late 1800s and early 1900s, construction of a number of dams and impoundments within the watershed to provide hydroelectric power generation as well as water supplies for agricultural and municipal usage substantially altered the hydrologic regime of the rivers in terms of the seasonal timing and magnitude of instream flows. The dams also created completely impassable barriers to the upstream migration of adult salmonids, thereby precluding access to otherwise suitable spawning and juvenile rearing habitat located farther upstream within the watershed. The construction of various dams and impoundments coupled with land use changes within the watershed cumulatively contributed to the declining abundance of Chinook salmon, ultimately leading to the extirpation of both spring-run and fall-run Chinook salmon on the mainstem San Joaquin River downstream of Friant Dam. Fall-run Chinook salmon continued to persist within the three major tributaries to the San Joaquin River, the Stanislaus, Merced, and Tuolumne Rivers, within habitat reaches downstream of major dams on each of these three tributaries. In addition to naturally spawning, self-sustaining populations of Chinook salmon within the three tributaries, a mitigation hatchery was constructed on the Merced River for the production of Chinook salmon, which has also contributed to the population abundance and dynamics of Chinook salmon within the lower watershed.

Since completion of the major dams in the San Joaquin River watershed during the late 1940s, the Chinook salmon population inhabiting the Tuolumne, Merced, and Stanislaus Rivers has been characterized by highly variable and fluctuating numbers of adult salmon returning to the tributaries each year to spawn. Adult Chinook salmon population abundance within the three tributaries over the past six decades has fluctuated from a low of several hundred fish to a high of over 40,000 adult salmon. Recent fall-run Chinook salmon escapement averages from 1992 through 2006 were 3,700 adults for the Stanislaus River, 4,600 for the Tuolumne River, and 3,800 for the Merced River. Maximum fall-run escapement over the period from 1967 to 2006 was between 10,000 and 14,000 adults for the Stanislaus River, between 10,000 and 20,000 for the Tuolumne River, and between

10,000 and 15,000 for the Merced River. The fluctuations in adult abundance appear to follow a long-term cyclical pattern, which has been hypothesized to be related to a variety of environmental factors. During the two most recent years, 2006 and 2007, adult Chinook salmon returns to the three tributaries have declined substantially to near-record lows.

There is a high degree of uncertainty and disagreement about the causal mechanisms that have contributed to the high fluctuations in adult returns to the Tuolumne River and other San Joaquin River tributaries. Research on the Tuolumne River suggests that numerous in-river mortality factors may be affecting the abundance and survival of Chinook salmon within the Tuolumne River and other tributaries, including the following: predation by piscivorous fish such as largemouth and smallmouth bass, striped bass, and Sacramento pikeminnow, both within the river and associated with gravel pits; exposure to seasonally elevated water temperatures, particularly during drier water years; low water velocities; habitat degradation within the tributaries; reduced instream flows supporting spawning, egg incubation, juvenile rearing, and adult and juvenile migration; redd superimposition; lack of turbidity during smolt outmigration; and limitations on available juvenile rearing habitat.

It appears that much of the fry and smolt mortality takes place after the juvenile Chinook salmon emigrate from the tributary rivers to the mainstem San Joaquin River, the Delta, or the ocean where there are a number of adverse conditions. Potential sources of mortality within the mainstem San Joaquin River and Delta include exposure to seasonally elevated water temperatures; exposure to potential entrainment risk at unscreened water diversions; entrainment and salvage risk as a result of operation of the State Water Project (SWP) and Central Valley Project (CVP) water export facilities; exposure to contaminants and toxics; vulnerability to predation mortality by striped bass, largemouth bass, Sacramento pikeminnow, and other predatory fish and birds; and delays in adult and juvenile migration as a result of changes in Delta hydrologic conditions associated with water export operations. In addition, the availability of suitable food supplies may be reduced for emigrating juvenile salmon within the lower San Joaquin River and the Delta. Furthermore, the results of correlation analyses between hydrologic conditions within the San Joaquin River basin during the spring period of juvenile emigration and the subsequent number of adult Chinook salmon returning to the tributaries two and one-half years later suggest the importance of river flow as a factor affecting the survival of juvenile Chinook salmon as they migrate downstream from the San Joaquin River tributaries through the lower mainstem and Delta.

There is growing scientific evidence that coastal oceanographic conditions, such as changes in water currents, changes in ocean water temperatures, and changes in ocean upwelling, are important influences on coastal productivity. They affect the species composition and abundance of zooplankton, macroinvertebrates, and fish inhabiting coastal marine waters. Changes in oceanographic conditions and coastal productivity have been related to salmon survival and ultimately the population abundance of adults. Within Pacific coastal waters, changes in oceanographic conditions associated with the Pacific decadal oscillation have been used to predict the abundance of returning adult Chinook salmon to inland tributaries to spawn. Ocean commercial and recreational harvesting of adult Chinook salmon has also

been identified as a factor affecting the population dynamics and abundance of Central Valley Chinook salmon stocks.

Concern has been expressed that the hatchery production of Chinook salmon in the Merced River and other Central Valley hatcheries could affect the genetic integrity and population dynamics of Chinook salmon stocks within the San Joaquin River watershed and throughout the Central Valley. The NMFS and CDFG are working cooperatively to identify hatchery management practices that will reduce the potential effects of hatchery production on the genetic integrity of Central Valley Chinook salmon populations, as well as the potential effects of hatchery planting practices and the ocean harvesting of hatchery-produced salmon on the health and abundance of wild in-river Chinook salmon produced within the Central Valley tributaries.

A variety of scientific investigations and management programs have been implemented recently in an effort to better understand the factors affecting the survival and population dynamics of Chinook salmon within San Joaquin River tributaries, including the Tuolumne River, as well as programs designed to protect and enhance habitat conditions for Chinook salmon spawning, egg incubation, juvenile rearing, and adult and juvenile migration. For example, the Vernalis Adaptive Management Program (VAMP, described in WSIP PEIR pp. 5.2-17 and 5.2-18; see Appendix B of this EIR) was specifically designed to: (1) provide improved protection and survival of juvenile Chinook salmon emigrating from the San Joaquin River tributaries through the Delta during the spring months, and (2) provide a scientific framework for testing and evaluating the potential relationship between changes in stream flows within the San Joaquin River at Vernalis, installation of the Head of Old River barrier, and reductions in SWP and CVP export rates during the spring months on juvenile Chinook salmon survival. The VAMP investigations are ongoing.

Investigations have also been conducted to monitor the seasonal loading and concentrations of various toxics and potential pollutants within the mainstem San Joaquin River and its tributaries. Land use within the San Joaquin River watershed includes both urban populations and extensive agricultural production. Runoff within the watershed may include a variety of water quality contaminants, including pesticides and herbicides, petroleum products, selenium, and salts. Scientific investigations in combination with various regulatory programs have been designed to characterize the potential effects of these water quality constituents on the health and survival of aquatic resources, including San Joaquin River basin Chinook salmon, as well as to identify management actions to reduce or avoid the potential risk of exposure to these water quality constituents.

Large-scale management and habitat restoration programs, such as the CALFED Bay-Delta Program, have invested substantial staff and financial resources in conducting scientific investigations and in supporting habitat enhancement and improvement projects designed to benefit Chinook salmon and other aquatic resources in the lower Tuolumne River and other Central Valley rivers. In addition, the Anadromous Fish Restoration Program under the Central Valley Project Improvement Act has invested substantial time and financial resources to improve the scientific understanding of various factors affecting Chinook salmon in the

San Joaquin River tributaries as well as to implement various management actions and habitat restoration and enhancement programs designed to improve the quality and availability of suitable habitat for Chinook salmon and other fish species.

One of the potentially significant environmental factors that affects habitat quality and availability within the Tuolumne River and other San Joaquin River tributaries for Chinook salmon spawning, egg incubation, juvenile rearing, and adult and juvenile migration is exposure to seasonally elevated water temperatures. A variety of scientific programs designed to develop simulation and predictive models have been implemented in recent years; these models can be used to assess the effects of various reservoir operating strategies, stream flow schedules, coldwater pool management strategies, and other factors influencing the seasonal and longitudinal gradients of water temperatures within the tributaries that potentially affect the health and survival of Chinook salmon in the watershed.

As part of previous State Water Resources Control Board Bay-Delta water quality and water-right proceedings as well as the Federal Energy Regulatory Commission (FERC) hydroelectric project relicensing, considerable emphasis has been placed on evaluating and potentially modifying instream flow schedules for the Tuolumne River and other San Joaquin River tributaries. These management changes to instream flows were intended to improve the physical habitat for various life-history stages of Chinook salmon and other fishery resources as well as to provide more suitable seasonal water temperature conditions in an effort to improve the overall health and survival of Chinook salmon. Investigations into the relationship between instream flows and the hatching success, abundance of fry, abundance of smolts, juvenile emigration survival, and ultimately the abundance of adult Chinook salmon returning to the tributaries to spawn are continuing.

Ongoing investigations are also being performed by the CDFG, NMFS, and the Pacific Fishery Management Council to better identify the effects of recreational and commercial harvesting of Chinook salmon from various river systems, including the Tuolumne River, on population dynamics and adult escapement. Since the Central Valley Chinook salmon populations are comprised of both naturally spawning, in-river-produced salmon and fish produced within the Central Valley hatcheries, including the Merced River Fish Hatchery, regulation of commercial and recreational harvesting is an important factor in protecting weaker stocks, such as the wild, inriver Chinook salmon produced in the Tuolumne River. Since 2007, a large-scale constant fractional marking program has been implemented at Central Valley hatcheries to provide additional information on the contribution of various hatcheries to adult salmon populations in the ocean, the effects of harvest on various salmon stocks, adult straying among Central Valley rivers, and the relationship between various environmental factors within the rivers, the Delta, and ocean environments that ultimately affect the health and survival of Central Valley populations.

In recent years, a settlement was reached in federal court that is intended to restore instream flows and self-sustaining populations of spring-run and fall-run Chinook salmon to the mainstem San Joaquin River downstream of Friant Dam. The San Joaquin River Restoration Program is in its early stages, but has identified a number of physical features within the

mainstem of the San Joaquin River that need to be modified or altered in order to reestablish Chinook salmon populations. The restoration program is seeking funding to implement the various restoration elements of the program, which are ultimately expected to support long-term fishery restoration within the river. There are, however, a number of uncertainties regarding the performance and effectiveness of the proposed restoration actions as well as the relationship between Chinook salmon populations and physical habitat within the mainstem and the survival of fall-run Chinook salmon inhabiting the lower tributaries. Full implementation of the San Joaquin River Restoration Program is expected to take a decade or longer.

Currently, the California Department of Water Resources and U.S. Bureau of Reclamation are engaged in a formal Section 7 consultation with the U.S. Fish and Wildlife Service regarding the potential effects of SWP and CVP export operations on the health and survival of delta smelt. The NMFS is responsible for issuing biological opinions under the Federal Endangered Species Act regarding the coordinated operations of the SWP and CVP for the protection of listed stocks of Chinook salmon, steelhead, and green sturgeon. The current Section 7 re-consultation process is expected to result in modifications to SWP and CVP export operations and other facilities within the Delta estuary, such as installation of the Head of Old River barrier and the south Delta barrier project, which may also have direct and indirect effects on the survival of juvenile Chinook salmon emigrating from the San Joaquin River tributaries downstream through the Delta.

The environmental and biological factors affecting the abundance of adult Chinook salmon returning to spawn in the Tuolumne River and other San Joaquin tributaries are dynamic and vary within and among years. An understanding of these various factors and their associated level of uncertainty provides, in part, the framework used in the PEIR to assess potential impacts of the WSIP operations on habitat quality and availability for various life-history stages of Chinook salmon inhabiting the lower Tuolumne River.

The commenter also addresses impacts to steelhead due to diversion of water from the Tuolumne River and that the WSIP could further reduce the range of the federal threatened Central Valley steelhead. Additional discussion from the WSIP PEIR on the potential impacts to steelhead has been included below. Section 5.3.6.1 of the WSIP PEIR (pp. 5.3.6-1 to 5.3.6-24; see Appendix B of this EIR) provides setting information and discussion on the presence of steelhead trout in the Tuolumne River. The data presented in the WSIP PEIR on habitat conditions in the lower Tuolumne River indicate that this reach of the river is unsuitable for significant populations of steelhead trout due to high temperatures over summer months. The studies by FERC (1996) concluded that no significant populations of steelhead or rainbow trout are present within the lower Tuolumne River system.

The McEwan study (2001) includes a discussion on the historical distribution of steelhead and documents historical evidence of steelhead in the lower Tuolumne River. The study also estimates the present range of likely steelhead occurrence, including in the Tuolumne River. Consistent with the WSIP PEIR, the McEwan study states that high water temperatures are a primary stressor for juvenile steelhead through the summer months. Dam construction over

the last century has made coldwater spawning and rearing habitat at mid-range and high elevations in the Tuolumne River watershed inaccessible to steelhead. Steelhead are now confined to the lower elevation reaches, where high summer water temperatures are a major stressor (McEwan, 2001).

Additionally, consistent with the WSIP PEIR, McEwan found that no significant populations of steelhead/rainbow trout are present in the lower Tuolumne River system. Section 5.3.6.1 of the WSIP PEIR presents the findings of rainbow trout surveys conducted between 1982 and 2004. These findings concluded that, while rainbow trout are present and their range has been moderately extended downstream as a result of FERC Settlement Agreement flows, large anadromous steelhead occur in the system very infrequently. Also consistent with the WSIP PEIR, McEwan presents data from surveys on the Tuolumne River that established the presence of rainbow trout. However, the surveys (conducted by a CDFG biologist in 2001) documented only a single rainbow trout of 28 inches and a single steelhead smolt of 11 inches, captured in the same location within a few days of each other. These findings by McEwan (2001) on steelhead presence in the lower Tuolumne River are consistent with those provided in the WSIP PEIR in showing that no significant populations of steelhead are present within the lower Tuolumne River system.

Table 5.3.1-3 in the WSIP PEIR shows current minimum stream flow requirements for the Tuolumne River below La Grange Dam (WSIP PEIR p. 5.3.1-12; see Appendix B of this EIR). The minimum flows are a condition of the license issued by the FERC in 1996 for the Don Pedro Project. Various other conditions are contained in the settlement agreement that led to issuance of the license, including a requirement that water quality and fish populations be monitored and certain fish habitat restoration projects completed. The Don Pedro Project is scheduled for relicensing in 2016, at which time the FERC will review the results of the monitoring program and the minimum instream flow requirements. Several commenters to the WSIP Draft PEIR indicated that because fall-run Chinook salmon populations in the Tuolumne River below La Grange Dam have declined in the last 10 years, it is likely that the FERC will increase the minimum instream flow requirements. Therefore, these commenters stated that the analysis of the WSIP in the Draft PEIR should have allowed for an increase in minimum flows. The WSIP PEIR did not incorporate a possible increase in the future minimum flow requirement in its primary analysis of the WSIP (WSIP PEIR Section 5.3.6; see Appendix B of this EIR), although it did consider the possibility of an increase in the future minimum flow requirement in the cumulative impact analysis (WSIP PEIR Section 5.7; see Appendix B of this EIR). The PEIR did not include an increase in the future minimum instream flow in its primary analysis of the WSIP for two reasons. First, it is impossible to predict what the future minimum instream flow requirements might be, and to assume flow requirements other than the current minimum flows would be speculative. Secondly, an increase in the minimum instream flows would likely have both beneficial and adverse effects on salmonids. Increased stream flow would likely benefit salmonids at times, such as providing increased quality and quantity of spawning and rearing habitat, but would also cause Don Pedro Reservoir to be drawn down farther than it is under the current minimum flow regime. This would reduce the magnitude of pulse flows in excess of the minimum required during the winter months and delay the typical large spring release during

the snowmelt period. The changes in pulse flows and the delay in spring release could harm salmonids. The delay in spring release due to an increase in the minimum flow requirement would be additive to the delay in spring release caused by the WSIP, producing a longer delay than the WSIP alone. The combined delay would have a more severe adverse effect on salmonids in the river below La Grange Dam than the WSIP alone. Therefore, while the Draft PEIR acknowledges that the FERC relicensing process will likely result in minimum flow requirements remaining the same or increasing, the San Francisco Planning Department determined that, in the absence of any information, the most reliable (and least speculative) assumption to use in the impact analysis was the existing, known minimum instream flow requirements.

[S-CDFG-03]

The commenter requests that SFPUC use alternative water sources other than the Tuolumne River system and uses the Modified WSIP as an example.

The commenter raises the Modified WSIP Alternative as an environmentally superior alternative to the WSIP. As discussed in SFPUC Resolution No. 08-0200, water supply sources in both the Modified WSIP Alternative and the Phased WSIP are similar, but differ in a few respects. First, the Modified WSIP Alternative proposes to divert an additional annual average of 15 mgd from the upper Tuolumne River compared to existing conditions through 2030 and thus would result in diverting more water from the upper Tuolumne River than would occur under the Phased WSIP through 2018. Under the Modified WSIP Alternative, water would be diverted at Hetch Hetchy Reservoir to meet 2030 demand. That diversion would result in reduced inflow to Don Pedro Reservoir, which, under the Modified WSIP Alternative, would be offset by reduced outflow from Don Pedro because of conservation measures undertaken by MID or TID (and/or in the service area of another nearby water agency). Water releases from Don Pedro Reservoir to the lower Tuolumne River thus would be similar to existing conditions under the Modified WSIP Alternative. The Phased WSIP proposes long-term increases in diversions of about 2 mgd, average annual, from the Tuolumne River to meet the WSIP reliability and drought rationing objectives and would maintain total deliveries to customers from the watersheds at an annual average of 265 mgd. In the short term, the Phased WSIP may result in the need to deliver more than a total of 265 mgd, average annual, to customers for a limited period while local conservation, recycling, and groundwater programs are being implemented. In the event the Phased WSIP delivers more than an average annual of 265 mgd from the watersheds, WSIP PEIR Mitigation Measure 5.3.6-4a will be implemented for the Lower Tuolumne River. If Mitigation Measure 5.5.6-4a proves infeasible, Mitigation Measures 5.3.6-4b and 5.3.7-6 will be implemented.

Second, the approach to the dry-year transfer is slightly different for the Modified WSIP Alternative and the Phased WSIP. The Westside Groundwater Basin conjunctive use program would provide a supplemental dry-year water supply source for both the Phased WSIP and the Modified WSIP Alternative. The dry-year water transfer from TID and MID under the Modified WSIP Alternative would be a transfer made only from conserved water (approximately 17.5 mgd average over the design drought). The Phased WSIP does not rule out the possibility of using conserved water only, and includes preferred Mitigation Measure

5.3.6-4a to be implemented if average annual deliveries of water from the watersheds exceeds 265 mgd, but it does not require that dry-year transfers be conserved water only (approximately 2 mgd average over the design drought). Thus, the substantially reduced size of the dry-year transfer under the Phased WSIP compared to the Modified WSIP Alternative combined with the urgency of undertaking the improvements and increasing reliability through implementation of the dry-year supply measures make it difficult to require that no transfer occur without equal and balancing conservation measures in MID/TID service area at this time.

Third, the Phased WSIP proposes more conservation, recycling and groundwater programs than the Modified WSIP Alternative. Both the Modified WSIP Alternative and the Phased WSIP assume 10 mgd of conservation, recycling, and groundwater programs in San Francisco. While the Modified WSIP Alternative commits to 5 to 10 mgd of additional conservation, recycling, and groundwater programs in the wholesale customer area through 2030, the Phased WSIP requires that a minimum of 10 mgd of additional conservation, recycling, and groundwater programs be implemented in the wholesale customer area by 2018.

The Modified WSIP Alternative would result in more impacts on the upper Tuolumne River watershed than the Phased WSIP, but possibly fewer impacts on the lower Tuolumne River watershed if under the Phased WSIP, average annual deliveries from the watersheds were to exceed 265 mgd in the short term.

The Modified WSIP Alternative would lessen but not entirely eliminate potential impacts on the lower Tuolumne River, but the impacts would be considered less than significant. As long as average annual deliveries from the watersheds do not exceed 265 mgd under the Phased WSIP, impacts on the lower Tuolumne River would be considered less than significant; mitigation measures will be implemented any time the SFPUC's average annual deliveries from the watersheds exceed an average annual total of 265 mgd. The SFPUC recognized that WSIP Mitigation Measure 5.3.6-4a is the preferred mitigation measure and should be undertaken as part of the Phased WSIP. The SFPUC did not close the door on the possibility of a dry-year "conserved water" transfer from TID and MID.

[S-CDFG-04]

The commenter states that participation in the San Joaquin Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) should include, but not be limited to, 3.2 acres of permanent conversion of California annual grassland.

Implementation of the project would be expected to result in temporary and permanent impacts to California grassland at both the Tesla Portal and Thomas Shaft sites as described on pp. 4.6-23 and 4.6-27 of the Draft EIR. However, the analysis in the Draft EIR (Impact 4.6-2) concludes that temporary impacts to California annual grassland habitat from construction disturbance would be less than significant with the implementation of Mitigation Measures 4.6-1a, 4.6-1b and 4.6-2, which require participation in the SJMSCP, implementation of best management practices during construction, and returning site to pre-

construction condition. SFPUC's SJMSCP Agreement includes compensation for the total acres of disturbed habitat anticipated for the project including both temporary and permanent impacts. As a participant in the SJMSCP, the SFPUC would remit a fee for compensatory mitigation related to the total acres of expected habitat disturbance (15.89 acres for both the Tesla Portal and Thomas Shaft sites). This area of disturbance was calculated as follows:

Permanent Impacts:

- 3.2 acres California annual grasslands
- 0.01 acre ruderal/disturbed land

Temporary Impacts:

- 11.72 acres California annual grassland
- 0.96 acre ruderal/disturbed land

TOTAL 15.89 acres

In SFPUC's SJMSCP Agreement, the San Joaquin Council of Governments (SJCOG) assigns this acreage to the two sites as follows: 15.77 acres at the Tesla Portal site and 0.12 acre at the Thomas Shaft site.

In addition, Mitigation Measure 4.6-2 requires that soils and/or vegetation disturbed or removed on the project site during construction be restored to the pre-construction conditions. This requires the restoration of original grade where possible, light compaction of loose soils or aeration of compacted soils, and reseeding with native grasses as necessary. Therefore construction-related impacts to California annual grassland are expected to be temporary and not contribute to a permanent loss of habitat on site, and would be considered less than significant. The project would result in permanent impacts that would be mitigated via SFPUC's SJMSCP Agreement (Mitigation Measure 4.6-1a). The cumulative analysis in the Draft EIR assumes that these measures would be effective, and while the loss of California annual grassland could be considered a potentially significant cumulative impact, the project's contribution (3.2 acres of permanent impact with compensatory mitigation) would not be considered cumulatively considerable.

The Mitigation Measure 4.6-1a presented on pp. 5-4 and 5-5 of the Draft EIR is revised for clarity as follows:

Participate in the SJMSCP

Mitigation Measure 4.6-1a: Prior to the commencement of construction activities, SFPUC shall coordinate with the Joint Powers Authority (JPA)/Technical Advisory Committee (TAC), implement relevant ITMMs for applicable species (as identified in Mitigation Measures 4.6-3b through 4.6-3l, below) and pay any necessary fees to fund offsite compensation under the terms

of the SJMSCP to provide replacement values that are equal to that of the permanent loss of ~~0.308~~ 3.2 acres of California annual grasslands and 0.01 acre of ruderal/disturbed land, and temporary impacts to 11.72 acres of California annual grassland and 0.96 acre of ruderal/disturbed land ~~habitat values of the artificial wetland, the temporary loss of <0.001 acre of ephemeral drainage, the temporary loss and permanent conversion of natural lands~~, and incidental take authorization for special-status species.

[S-CDFG-05]

The commenter states that during construction, the access road to the Thomas Shaft site should not be modified in any way that could impact Mt. Diablo cottonweed. The comment is noted; there will be no road improvements to the access road to the Thomas Shaft site under this project. No change to the Draft EIR is required.

[S-CDFG-06]

The commenter refers to data presented in a technical report cited in the EIR. This report, titled "San Joaquin Regional Water Quality Improvement Project Biological Resources Report" was prepared by May & Associates in May 2008 in support of the EIR. Table 7 of Appendix A (on page 55) of this technical report included a list of species identified on site during a survey conducted in the summer of 2007. At that time specific *Amisinckia* species could not be identified because the plants were not flowering. Subsequent surveys conducted in February 2008 confirmed that the fiddleneck species present were: *Amsinckia menziesii* var. *intermedia*, *Amsinckia eastwoodiae*, and *Amsinckia menziesii*. None of these species are state or federal special-status species.

Tables 3 and 6 of the May & Associates report correctly state that no rare fiddleneck species (*Amsinckia lunaris* or *Amsinckia grandiflora*) were identified on the Tesla Portal or Thomas Shaft sites. This is also the information presented in the Draft EIR in Table 4.6-1 on pages 4.6-7 and 4.6-8 and in Appendix C of the Draft EIR.

Therefore the information presented in the Draft EIR is accurate and no changes to the Draft EIR are required.

[S-CDFG-07]

The commenter notes that any temporary impacts that could result in the potential permanent loss of habitat should be considered as permanent impacts. As discussed in response to comment S-CDFG-04 above, implementation of Mitigation Measures 4.6-1a, 4.6-1b, and 4.6-2, which require participation in the SJMSCP, implementation of best management practices during construction and returning site to pre-construction condition, would be expected to mitigate temporary impacts to California annual grassland on both sites and therefore, temporary impacts are not expected to contribute to a permanent loss of habitat on site. The SFPUC's SJMSCP Agreement includes compensatory mitigation (in the form of in lieu fees) for 15.89 total acres of disturbance (both permanent and temporary), including California grassland habitat and ruderal habitat at the Tesla Portal and Thomas Shaft sites. In the agreement, the SJCOG assigns the mitigation breakdown of the acreage to the two sites as follows: 15.77 acres at Tesla Portal and 0.12 acre at Thomas Shaft.

Please see the response to S-CDFG-04 for changes made to Mitigation Measure 4.6-1a that provide additional clarification to the mitigation measure.

[S-CDFG-08]

The commenter addresses mitigation for impacts to special-status wildlife species. The SFPUC will participate in the SJMSCP and as such, the mitigation measures in the Draft EIR for the SJRWQIP were developed to be consistent with the Incidental Take Minimization Measures (ITMMs) as outlined in the SJMSCP (SJCOG, 2000). On October 10, 1994, SJCOG, Caltrans, USFWS, CDFG, and the cities of Escalon, Lathrop, Lodi, Manteca, Ripon, Stockton, and Tracy signed a memorandum of understanding that established the objectives of the SJMSCP. The SJMSCP identifies USFWS and CDFG as permitting agencies as defined in Section 1.19 Permitting Agencies and Section 8.1.1 Permitting Agencies.

As stated in Section 1.1.7 on page 1-12 of the SJMSCP:

> "The SJMSCP intends to provide comprehensive compensation for impacts to threatened, endangered, rare and unlisted SJMSCP Covered Species and other wildlife and compensation for some non-wildlife related impacts to recreation, agriculture, scenic values and other beneficial Open Space uses. At the state and federal levels, the SJMSCP is expected to provide adequate compensation for impacts to plants, fish and wildlife for SJMSCP pursuant to the California Endangered Species Act (CESA), the California Native Plant Protection Act, the Federal Endangered Species Act (ESA), Section 404 of the Federal Clean Water Act (CWA), Section 10 of the Rivers and Harbors Act of 1899, and the Migratory Bird Treaty Act (MBTA) for ESA-listed SJMSCP Covered Bird Species also protected under this Act as these laws relate to the California Department of Fish and Game's (CDFG), United States Fish and Wildlife Service's (USFWS), and the U.S. Army Corps of Engineers' (USACE) responsibilities for Covered Species with respect to SJMSCP Permitted Activities located within the boundaries of San Joaquin County."

The proposed project is considered a "permitted activity" under the SJMSCP, and therefore the mitigation identified by the SJMSCP Joint Powers Authority (JPA) and included in the SFPUC's SJMSCP Agreement for this project is sufficient to address potential impacts under CEQA to species covered by the SJMSCP.

[S-CDFG-09]

The commenter requests that preconstruction surveys for San Joaquin kit fox be conducted within 14 days of the start of construction. Mitigation Measure 4.6-3c, Implement Incidental Take Minimization Measures for the San Joaquin Kit Fox, states that preconstruction surveys will be conducted 14 to 30 days prior to the commencement of ground disturbance. The survey timing stated in the mitigation measure is consistent with the SJMSCP ITMMs, SFPUC's SJMSCP Agreement, and the USFWS Standardized Recommendations for Protection of the San Joaquin Kit Fox Prior to or during Ground Disturbance. Therefore, no changes to the Draft EIR are necessary.

Mitigation Measure 4.6-3c outlines the San Joaquin kit fox protection measures that will be implemented prior to and during project construction to reduce potential impacts to San Joaquin kit fox, consistent with the SJMSCP ITMMs and SFPUC's SJMSCP Agreement. The mitigation measure outlines preconstruction survey methods. The mitigation measure does not include the protocol level surveys as described in the USFWS San Joaquin Kit Fox Survey Protocol for the Northern Range, which are typically implemented to determine whether kit fox are actively present in the project area. However for this project, it is assumed that kit fox may be present in the project area and therefore the mitigation measure adheres to kit fox protection measures. Mitigation Measure 4.6-3c outlines what measures would be undertaken should dens be identified during preconstruction surveys (differentiating between unoccupied dens, dens occupied by adults only and natal dens). The mitigation measure also outlines that the provisions of the USFWS Standardized Recommendations for Protection of the San Joaquin Kit Fox Prior to or During Ground Disturbance, will be followed should a den be identified during construction, based on the outcome of the preconstruction surveys. These measures are sufficient to reduce potential impacts to San Joaquin kit fox at both the Tesla Portal and Thomas Shaft sites to a less-than-significant level.

In addition, the commenter requests that biologists with specialized experience with San Joaquin kit fox conduct the required surveys. In response, Mitigation Measure 4.6-3c has been revised to explicitly identify that the qualified biologist would have experience with kit fox biology, identification, and survey techniques. Mitigation Measure 4.6-3c of the Draft EIR is revised as follows:

Implement Incidental Take Minimization Measures for San Joaquin Kit Fox

Mitigation Measure 4.6-3c: SFPUC shall implement the ITMMs identified for the San Joaquin kit fox under the SJMSCP to reduce the level of impact on the San Joaquin kit fox. Mitigation measures defined by the SJMSCP and the USFWS to protect the San Joaquin kit fox include the following:

- A qualified biologist with demonstrated experience in kit fox biology, identification, and survey techniques shall conduct preconstruction surveys two calendar weeks to 30 calendar days prior to commencement of ground disturbance. Surveys shall be conducted by qualified biologists. When surveys identify potential dens (potential dens are defined as burrows at least four inches in diameter which open up within two feet), potential den entrances shall be dusted for three calendar days to register track of any San Joaquin kit fox present. If no San Joaquin kit fox activity is identified, potential dens may be destroyed.

Mitigation Measure 4.6-3c as described in the Draft EIR is consistent with the measures as described by the USFWS Standardized Recommendations for Protection of the San Joaquin Kit Fox Prior to or During Ground Disturbance (USFWS, 1999) that apply to "Other Projects" as the commenter requests.

[S-CDFG-10]

The commenter addresses mitigation for potential impacts to burrowing owls. In response, Mitigation Measures 4.6-3e, 4.6-3f, and 4.6-3g, Conduct Pre-Construction Surveys for Burrowing Owls, have been revised for clarity and consistency and to be consistent, as applicable, with the SJMSCP and the California Burrowing Owl Consortium's Burrowing Owl Survey Protocol and Mitigation Guidelines (California Burrowing Owl Consortium, 1993), as follows:

Conduct Pre-Construction Surveys for Burrowing Owls

Mitigation Measure 4.6-3e: Breeding Season Surveys. ~~In January, and again no more than two weeks before construction, a survey for burrows and burrowing owls shall be conducted by a qualified biologist within 500 feet of the project (access permitting). The survey will conform to the protocol described by the California Burrowing Owl Consortium in the Burrowing Owl Survey Protocol and Mitigation Guidelines (California Burrowing Owl Consortium, 1993), which includes up to four surveys on different dates if there are suitable burrows present.~~

~~If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with the California Department of Fish and Game (CDFG), as to whether or not work will affect the occupied burrows or disrupt reproductive behavior.~~

~~If it is determined that construction will not affect occupied burrows or disrupt breeding behavior, construction will proceed without any restriction or mitigation measures.~~

~~If it is determined that construction will affect occupied burrows during August through February, the subject owls will be passively relocated from the occupied burrow(s) using one-way doors. There will be at least two unoccupied burrows suitable for burrowing owls within 300 feet of the occupied burrow before one-way doors are installed. Artificial burrows will be in place at least one week before one-way doors are installed on occupied burrows. One-way doors will be in place for a minimum of 48 hours before burrows are excavated.~~

~~If it is determined that construction will physically affect occupied burrows or disrupt reproductive behavior during the breeding season (February 1 through August 31), then avoidance is the only mitigation available. Construction will be stopped within 250 feet of occupied burrows until it is determined that the subject owls are not nesting or until a qualified biologist determines that juvenile owls are self-sufficient or are no longer using the natal burrow as their primary source of shelter.~~ Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below:

- If project schedule permits, a qualified biologist will survey for burrows and burrowing owls during the breeding season (February 1 to August 31), immediately preceding construction. Surveys will be conducted within 500 feet of the project boundary (access permitting) in accordance with the California Burrowing Owl Consortium (1993) guidelines or as otherwise determined by CDFG. Burrows would be inspected for signs of owl activity (tracks, pellets, feathers, etc.). The locations of burrowing owl sightings, occupied burrows, and burrows with signs of owl activity will be marked on a map of the project area at a scale sufficient to accurately show the distance of active burrows to the limits of construction. Surveys will be conducted on at least four separate dates during the breeding season in areas where suitable burrows are present. If possible, surveys will be conducted during the peak of the burrowing owl breeding season, generally between April 15 and July 15.

- If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with CDFG, as to whether work will affect the occupied burrows or disrupt reproductive behavior.

- If it is determined that construction will not affect occupied burrows or disrupt breeding behavior, construction will proceed without any restrictions or mitigation measures.

Mitigation Measure 4.6-3f: Winter Surveys. ~~During the non-breeding season (September 1 through January 31) burrowing owls occupying the project site should be evicted from the project site by passive relocation as described in the CDFG's Staff Report on Burrowing Owls (CDFG, 1995).~~ Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below:

- If birds are not observed during breeding season surveys, or if breeding season surveys are infeasible due to project scheduling, or if construction will occur during the wintering season, a winter survey will be conducted to identify non-breeding residents of the project site. Winter surveys will be conducted within 500 feet of the project site (access permitting) or as otherwise determined by CDFG during the period when wintering owls are most likely to be present (December 1 to January 31). The locations of burrowing owl sightings, occupied burrows, and burrows with signs of owl activity will be marked on a map of the project area at a scale sufficient to accurately show the distance of active burrows to the limits of construction.

- If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with CDFG, as to whether or not work will affect the occupied burrows.

- If it is determined that construction will not affect occupied burrows, construction will proceed without any restrictions or mitigation measures.

- If it is determined that construction will affect occupied burrows, the subject owls will be passively relocated from the occupied burrow(s) using one-way doors prior to the onset of breeding season. Owls will be encouraged to relocate to alternate burrows that are at least 160 feet from the construction limits. One alternate natural or artificial burrow for each burrow excavated will be in place at least one week before one-way doors are installed on occupied burrows. One-way doors will be in place for a minimum of 48 hours before burrows are excavated.

Mitigation Measure 4.6-3g: Fall Surveys.~~During the breeding season (February 1 through August 31) occupied burrows shall not be disturbed and shall be provided with a 100-foot protective buffer until and unless the TAC, with the concurrence of the Permitting Agencies' representatives on the TAC; or unless a qualified biologist approved by the Permitting Agencies verifies through noninvasive means that either: 1) the birds have not begun egg laying, or 2) juveniles from the occupied burrows are foraging independently and are capable of independent survival. Once the fledglings are capable of independent survival, the burrow can be destroyed.~~ Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below:

- If surveys must be conducted between September 1 and November 30 (which is outside of the time windows specified above), a qualified biologist will conduct a survey for burrows and burrowing owls no more than thirty (30) days prior to ground-disturbing activity. If necessary, resident owls will be passively relocated from occupied burrows, as described above. If construction activities are still ongoing beyond November 30, then winter surveys will be conducted during December and January.

[S-CDFG-11]

The commenter addresses mitigation related to Swainson's hawk and states that during construction a buffer of two times the dripline of a tree with an occupied Swainson's hawk nest is an arbitrary buffer distance. Mitigation Measure 4.6-3h, Conduct Pre-Construction Surveys for Swainson's Hawk, of the Draft EIR addresses the measures that will be implemented during project construction to mitigate potential impacts to Swainson's hawk. Mitigation Measure 4.6-3h is consistent with the SJMSCP ITMMs for Swainson's hawk and the SFPUC's SJMSCP Agreement, both of which state that if a nest tree becomes occupied during construction then a buffer of two times the dripline of the tree will be established. Also, per the SJMSCP, the mitigation measure states that if a nest is found during preconstruction surveys, then all construction activities shall remain at a distance of 1,320 feet, unless equally effective measures are agreed to by CDFG.

The commenter also requests that CDFG be notified to determine appropriate actions should Swainson's hawk be found nesting in the project area. Mitigation Measure 4.6-3h has been revised as follows:

Conduct Pre-Construction Surveys for Swainson's Hawk

Mitigation Measure 4.6-3h: A qualified biologist shall conduct a preconstruction survey for Swainson's hawk, prior to the commencement of any ground disturbing construction activities (e.g., grass/vegetation/brush/tree removal, soil excavation, grading, vehicle access, staging of materials or vehicles, large scale materials off-haul or delivery, construction of temporary or permanent access roads).

In the case that Swainson's hawks are found nesting in the area, the SFPUC will notify CDFG. At a minimum~~In addition,~~ the following mitigations regarding Swainson's hawk, as listed from the SJMSCP, will be implemented:

- If a nest tree becomes occupied during construction activities, then all construction activities shall remain a distance of two times the dripline of the tree, measured from the nest.

- If any nest trees need to be removed, they may be removed between September 1 and February 15, when the nests are unoccupied.

The following two measures will also be implemented:

- If any unoccupied nests are found during preconstruction surveys, these nests may be removed when the nests are unoccupied.

- If any occupied nests are found during preconstruction surveys, then all construction activities shall remain at a distance of ¼ mile (1,320 feet), unless CDFG agrees to other equally effective measures~~ are agreed to by CDFG~~ (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc).

[S-CDFG-12]

The commenter addresses mitigation for potential impacts to white-tailed kite. Mitigation Measure 4.6-3j, Implement Incidental Take Minimization Measures for White-Tailed Kite, in the Draft EIR is consistent with the SJMSCP ITMM with respect to establishing a setback of 100 feet from white-tailed kite nesting areas as mitigation for the SJRWQIP. The commenter requests that CDFG be notified of the proposed buffer zone. Mitigation Measure 4.6-3i in the Draft EIR has been revised as follows:

Implement Incidental Take Minimization Measures for White-Tailed Kite

Mitigation Measure 4.6-3i: SFPUC shall implement the ITMM identified for the white-tailed kite under the SJMSCP, which consists of the following:

- A qualified biologist shall conduct preconstruction surveys and investigate all potential nesting trees on the project site (e.g., especially tree tops 15-59 feet above the ground in oak, willow, eucalyptus, cottonwood, or other deciduous trees), during the nesting season (February 15 to September 15) whenever white-tailed kites are noted on site or within the vicinity of the project site during the nesting season.

- If the species is found nesting, a setback of 100 feet from nesting areas shall be established and maintained during the nesting season for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective measures ~~are agreed to by CDFG~~ (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc.) and CDFG shall be notified of the proposed buffer zone. This setback applies whenever construction or other ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.

[S-CDFG-13]

The commenter requests that CDFG be notified of the proposed buffer zone for the California horned lark. Mitigation Measure 4.6-3j, Implement Incidental Take Minimization Measures for California Horned Lark and Northern Harrier, in the Draft EIR incorporates a 500-foot setback from nesting areas and is consistent with the SJMSCP ITMMs and SFPUC's SJMSCP Agreement. Mitigation Measure 4.6-3j in the Draft EIR has been revised as follows:

Implement Incidental Take Minimization Measures for California Horned Lark and Northern Harrier

Mitigation Measure 4.6-3j: SFPUC shall implement the ITMM identified for the California horned lark and northern harrier under the SJMSCP, which consists of the following:

- A qualified biologist shall conduct a preconstruction survey and investigate all potential nesting trees to determine the presence or absence of the species on the project site.

- If species are found, a setback of 500 feet from nesting areas shall be established and maintained during the nesting season (February 16 – August 31) for the period encompassing nest building and continuing until

fledglings leave nests, unless CDFG agrees to other equally effective measures ~~are agreed to by CDFG~~ (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc.), or offsite compensation shall be provided, and CDFG shall be notified of the proposed buffer zone. If a setback is used, this setback would apply whenever construction or other ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.

[S-CDFG-14]

The commenter requests that CDFG be notified to determine the appropriate actions should any golden eagle nest be discovered on site. Mitigation Measure 4.6-3k, Conduct Pre-Construction Surveys for Golden Eagle, in the Draft EIR incorporates a 500-foot setback from golden eagle nesting areas and is consistent with the SJMSCP ITMMs. Mitigation Measure 4.6-3k in the Draft EIR has been revised as follows:

Conduct Pre-Construction Surveys for Golden Eagle

Mitigation Measure 4.6-3k: Prior to the start of construction, a qualified biologist shall conduct golden eagle surveys as required by the SJMSCP. Additionally, SFPUC shall implement the ITMM identified for the golden eagle under the SJMSCP, which consists of the following:

- When a site inspection indicates the presence of a nesting golden eagle, CDFG will be notified and a setback of 500 feet from the nesting area shall be established and maintained during the nesting season (normally approximately February 1 – June 30) for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective measures ~~are agreed to by CDFG~~ (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc). This setback applies whenever construction or other ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.

[S-CDFG-15]

The commenter requests that should species be found, a setback of 500 feet from nesting areas be established and CDFG should be notified of the proposed buffer zone. Mitigation Measure 4.6-3l, Conduct Pre-Construction Surveys for Ferruginous Hawk and Prairie Falcon, in the Draft EIR identifies that in the highly unlikely event that the species are found nesting on a project site, ITMMs shall be formulated prior to ground disturbance by the TAC and approved by the JPA with the concurrence of the Permitting Agencies' representatives on the TAC in accordance with the SJMSCP's Adaptive Management Plan. The SJMSCP identifies CDFG as permitting agency of the plan and whose representative on the TAC would need to

concur with ITMMs developed by the TAC and approved by the JPA. This mitigation is consistent with the SJMSCP ITMMs. Mitigation Measure 4.6-3l has been revised as follows:

Conduct Pre-Construction Surveys for Ferruginous Hawk and Prairie Falcon

Mitigation 4.6-3l: Prior to the start of construction, a qualified biologist shall conduct surveys for ferruginous hawk and prairie falcon as required by the SJMSCP. These species currently do not nest in San Joaquin County and are not expected to nest in the County over the life of the SJMSCP. Therefore, in the highly unlikely event that one of these species is found nesting on a project site, SFPUC shall notify CDFG of the proposed buffer zone and a setback of 500 feet from the nesting area shall be established and maintained for the period encompassing nest building and continuing until fledglings leave the nests, unless CDFG agrees to other equally effective measures. ITMMs shall be formulated prior to ground disturbance by the TAC and approved by the JPA with the concurrence of the Permitting Agencies' representatives on the TAC in accordance with the SJMSCP's Adaptive Management Plan. ITMMs may consist of preconstruction surveys, avoidance techniques, and buffer areas.

Dear Jamie Dean:

The State Clearinghouse submitted the above named Draft EIR to selected state agencies for review. On the enclosed Document Details Report please note that the Clearinghouse has listed the state agencies that reviewed your document. The review period closed on October 8, 2008, and the comments from the responding agency (ies) is (are) enclosed. If this comment package is not in order, please notify the State Clearinghouse immediately. Please refer to the project's ten-digit State Clearinghouse number in future correspondence so that we may respond promptly.

Please note that Section 21104(c) of the California Public Resources Code states that:

> "A responsible or other public agency shall only make substantive comments regarding those activities involved in a project which are within an area of expertise of the agency or which are required to be carried out or approved by the agency. Those comments shall be supported by specific documentation."

[01]

These comments are forwarded for use in preparing your final environmental document. Should you need more information or clarification of the enclosed comments, we recommend that you contact the commenting agency directly.

This letter acknowledges that you have complied with the State Clearinghouse review requirements for draft environmental documents, pursuant to the California Environmental Quality Act. Please contact the State Clearinghouse at (916) 445-0613 if you have any questions regarding the environmental review process.

Sincerely,

Terry Roberts

Project Title San Joaquin Regional Water Quality Improvement Project
Lead Agency San Francisco, City and County of

Type EIR Draft EIR

Description The San Francisco Public Utilities Commission (SFPUC) proposes to improve the disinfection capabilities of the Tesla Portal site and the Thomas Shaft site. The proposed Tesla Portal Disinfection Station would be located at the Tesla Portal site and includes closing the existing Tesla Portal Hypochlorite Station and the construction and operation of replacement facilities. Also at the Tesla Portal site, the project would include the construction and operation of a new Advanced Disinfection Facility that would pass water by a series of ultraviolet light arrays. At the Thomas Shaft site, the Lawrence Livermore Water Quality Improvements would upgrade water treatment facilities.

Dear Ms. Dean:

The California Department of Transportation (Department) appreciates the opportunity to have reviewed the Draft Environmental Impact Report (DEIR) for the proposed construction of the San Joaquin Regional Water Quality Improvement Project. This proposed project is to be located in the unincorporated San Joaquin County at two existing facility sites, the Tesla Portal site and the Thomas Shaft site along the SFPUC's regional water system.

The Department has no comments at this time.

If you have any questions or would like to discuss our comments in more detail, please contact Kathy Selsor at (209) 948-7190 (e-mail: kathy_selsor@dot.ca.gov) or me at (209) 941-1921.

Dear Ms. Dean:

Subject: Comments on Draft Environmental Impact Report for San Joaquin Regional Water Quality Improvement Project, SCH #2007052109, San Joaquin County

Department of Fish and Game (DFG) staff has reviewed the draft Environmental Impact Report (EIR) for the San Joaquin Regional Water Quality Improvement Project (Project). The San Francisco Public Utilities Commission (SFPUC) proposes to construct the above referenced Project. The proposed Project is located in unincorporated San Joaquin County at two existing facility sites, the Tesla Portal site and the Thomas Shaft site, along the SFPUC's regional water system. The Tesla Portal site includes Assessor's Parcel No. 253-160-02, Township 3S and Range 5E. The Thomas Shaft site includes Assessor's Parcel No. 251-330-10, Township 4S and Range 4E. At the Tesla Portal site, the existing building that contains the Tesla Portal Hypochlorite Station would be replaced with a new Chemical Process Building and Office/Control Building. An ultraviolet (UV) facility would be constructed, which would disinfect water using a series of UV light arrays. At the Thomas Shaft site, the Lawrence Livermore Water Quality Improvements would upgrade existing water treatment with a UV facility to meet disinfection requirements of the Surface Water Treatment Rule and the Long Term 2 Enhanced Surface Water Treatment Rule.

DFG, a Trustee Agency under the California Environmental Quality Act (CEQA), is responsible for the conservation, protection, and management of the State's biological resources. Pursuant to Fish and Game Code Section 1801, it is the policy of the State to encourage preservation, conservation, and maintenance of wildlife resources, including perpetuation of all species of wildlife for their intrinsic and ecological values. In addition, pursuant to Fish and Game Code Section 1802, DFG has jurisdiction over the conservation, protection, and management of fish, wildlife, native plants, and habitat necessary for biologically sustainable populations of those species. The purpose of DFG's comments is to provide guidance to the SFPUC to ensure that, if the Project under the Water System Improvement Program (WSIP) is implemented, biological resources are protected. Like the draft EIR, DFG has organized comments beginning with the WSIP and proceeding with comments by each respective section.

Project Description

The proposed Project would consist of the following components:

Tesla Treatment Facility (Tesla Portal Site)

- A 14,000-square-foot Chemical Process Building, 32 feet in height containing three 16,000-gallon sodium hypochlorite tanks, two 10,000-gallon fluoride tanks and two outdoor 12,500-gallon carbon dioxide (CO_2) tanks.

- A 3,500-square-foot Office/Control Building, 12 feet in height containing offices, control room, process room, laboratory, restrooms, lockers, shower, and a multipurpose room.

- A 20,000-square-foot UV Building, 32 feet in height containing 12 UV reactors (10 active and two standby) each with UV lamp arrays and various sensors on a floor recessed approximately 14 feet below-grade, below-grade piping vaults and two 3,000-gallon food-grade acid tanks.

- Other proposed improvements at the Tesla Portal site include a 90,000-gallon containment basin lined with rip rap to capture released water for grit removal and periodic maintenance (three times per month), two valve vaults to direct adequate flow, as required, two valve houses, and other infrastructure including a microwave tower up to 100 feet in height.

Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)

- Two UV reactors (one active and one standby) installed within the existing Chlorination Facility building.

- A 360-square-foot prefabricated structure 10 feet in height within the fenced area atop Thomas Shaft.

- A 2,500-gallon percolation water tank for processed water.

The proposed project would improve already existing uses (i.e., water treatment) at the two sites. The Lawrence Livermore Water Quality Improvements are being designed for a 0.165 million gallons per day (mgd) capacity. The proposed project would allow Lawrence Livermore National Laboratory (LLNL) to take up to 0.165 mgd of their annual average demand of 0.8 mgd from Thomas Shaft, and continue to receive the remainder of the water from Mocho Shaft, an SFPUC facility located downstream of the Thomas Shaft site. The amount of water supplied to LLNL would be consistent with the preexisting contract between the two parties.

Project Objectives

The objectives of the proposed Project consist of the following:

Tesla Treatment Facility (Tesla Portal Site)

- Replace existing water treatment facilities that are not currently seismically safe with new facilities that are designed to meet current seismic, safety/fire, and building code standards.

- Construct new water treatment facilities to meet U. S. Environmental Protection Agency (U. S. EPA) requirements for *Cryptosporidium* reduction/inactivation in drinking water, as required under the U. S. EPA's Long Term-2 Enhanced Surface Water Treatment Rule (LT2ESWTR).

- Improve current water quality management capabilities such as pH control.

Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)

- Construct new water treatment facilities to meet U.S. EPA requirements under the Surface Water Treatment Rule for the reduction/inactivation of *Giardia*, as well as assist in meeting LT2ESWTR *Cryptosporidium* requirements to enable delivery of potable water to LLNL from the Thomas Shaft of the Coast Range Tunnel.

- Continue to provide back-up chlorination capabilities.

Comments on Executive Summary

WSIP Water Supply Option, Pg. 1-6: Through the WSIP, the SFPUC proposes a water supply option to address the water supply level of service objective of meeting a projected 35 mgd increase in customer purchase requests by 2030, and to provide drought-year delivery with a maximum systemwide rationing of 20 percent. This strategy includes maximizing the use of local watershed supplies, increasing diversions from the Tuolumne River under existing water rights, and development of new local resources, including additional conservation, water recycling, and groundwater supply programs in San Francisco. This combination of water supply sources is expected to fully meet customer purchase requests during non-drought years through 2030.

On October 7, 2007, DFG provided comments to the draft Program Environmental Impact Report (PEIR) for the WSIP proposed by the SFPUC which included comments to the proposed water supply option. DFG reiterates the following comments as well as others in the PEIR as previously stated and provides new comments with respect to current information.

Lower Tuolumne River (Below New Don Pedro)

The PEIR states that the implementation of WSIP would have no impact on the current minimum instream flow requirement set by the Federal Energy Regulatory Commission (FERC) in the 1996 Fishery Settlement Agreement. DFG is concerned that the current FERC required flow regime (i.e., PEIR's CEQA baseline conditions) may not be sufficient to prevent salmon populations in the Tuolumne River from declining. In fact, we have evidence demonstrating that adult Tuolumne River fall-run Chinook salmon *(Oncorhynchus tshawytscha)* produced at a given spring flow has declined by about 50% (mean of 6,805

recruits) since the FERC Settlement Agreement was implemented in 1996. The decline is statistically significant based on an F-test comparison of two flow recruitment regression models: one based on the period from 1980 to 1990 and the other based on the period from 1998 to 2003. We believe that, as proposed, WSIP would make these conditions worse for Tuolumne River salmonids, thus exacerbating the current decline of this population. To address this concern, DFG wrote a letter dated August 1, 2007 to Secretary Kathleen Bose of the FERC and requested them to direct the Modesto Irrigation District and Turlock Irrigation District to provide higher magnitude and greater duration instream flows during the spring period of each year in order to assure acceptable salmon smolt survival and assure that the now critically-impaired salmon populations will remain intact until a new license is considered for Project 2299 in 2014. In this letter, DFG presents evidence, which is summarized below, that demonstrates strong correlations between this observed population decline and the conditions of reduced spring flow and elevated spring water temperature, as directly caused by the operations of Project 2299.

The CEQA environmental baseline conditions in the Lower Tuolumne River are essentially driven by the operations of Project 2299 which, for reasons we identify below, are creating conditions that are not suitable for the anadromous fisheries in the Tuolumne River. Although we recognize that the City and County of San Francisco are not the licensees for Project 2299, it is irrefutable that the actions of the SFPUC on the Tuolumne River at Early Intake, Cherry Valley Dam, and Hetch Hetchy and Lake Eleanor reservoirs influence the timing, duration, and magnitude of water releases from the New Don Pedro Dam. Increased diversion of waters from a river system which currently lacks sufficient flow to support sustainable anadromous fisheries including Federally Threatened Central Valley steelhead (*Oncorhynchus mykiss iridieus*) should be considered a significant cumulative impact (see Zimmerman et al. 2008). Although the proposed increase in diversion in itself may (arguably) not be deemed significant, when viewed in conjunction with Project 2299, existing SFPUC diversions, and other diversions from the Tuolumne River, the effects are cumulatively considerable [see CCR Title 14, Section 15065(a)(3)]. In this context, *we believe the proposed project has the potential to cause anadromous fish populations to drop below self-sustaining levels and further reduce the number and restrict range of Federally Threatened Central Valley steelhead* – thereby requiring a finding of significant effect [CCR Title 14, Section 15065 (a)(1)]. Therefore, we respectfully request the SFPUC use alternative water sources other than the Tuolumne River system to meet purchase requests in 2030 and drought year demands, at least until Project 2299 can properly address the inadequacies in the current flow regime for the purpose of creating, enhancing and supporting a sustainable anadromous fishery in the Lower Tuolumne River.

Documented Tuolumne River Salmon Population Decline

Strong evidence exists that the Tuolumne River fall-run Chinook salmon population has declined severely. Historically, this fall run was documented (U. S. Fish and Wildlife Service 1940) to annually exceed 72,000 escaping (i.e., spawning) adults. This number became reduced severely, coincidentally with, and in part caused by, water diversions and dams which were developed and operated on the Tuolumne River. Immediately prior to the operation of the New Don Pedro Project, fall-run Chinook salmon numbers annually reached 20,000 to 25,000 escaping adults, but unfortunately the instream flow and other

fishery protection measures included in the original Project 2299 license were inadequate to stem the continuing decline of salmon. By the time of the 1996 Fisheries Settlement Agreement, salmon numbers had progressively declined to less than 1,000 adults annually. This decline, both overall and when dissected into various lifestage survival components, very strongly correlates with Tuolumne River flow inadequacy during critical salmon life-stages.

In 1997, a record high water year produced substantial project spill, essentially rendering moot the fishery effects of Project 2299 water operations, as well as the effects of some of the out-of-tributary influences on juvenile salmon survival during that year. Absent those controlling influences, the salmon experienced much greater juvenile survival and downstream migration success. Accordingly, in 2000, when most of these fish returned to the Tuolumne River as adults, we documented runs well in excess of 18,000 individuals. Unfortunately, that benefit was short-lived. Since 2000, and after normal Project 2299 operations resumed, the Tuolumne River salmon escapements have again sharply declined. As of 2006, the Tuolumne River escapement population had dwindled to about 600 returning adults. This represents an order-of-magnitude salmon population reduction during the time when the Fishery Settlement Agreement flows and other "protective conditions" under that agreement were in full effect.

Subsequently, since comments were made to the PEIR in October 2007, in a report titled "Lower Tuolumne River Spawning Report, Spawning Survey Summary Update, March 2008" (Ford & Kirihara 2008), run size estimate for Tuolumne River Chinook for 2007 was 211 fish. The current run size of 211 fish with the declines experienced over recent years clearly show the Tuolumne River Chinook to be at *high risk of extinction*, (Lindley 2007). Additionally, USFWS issued a preliminary analysis which indicates that the Tuolumne River fall-run Chinook salmon population of naturally produced fish "is at a high risk of extinction because the instream flow releases are too low" (Mesick 2008). The report finds that "the Tuolumne River fall-run Chinook salmon population is at a high risk of extinction because the population of naturally produced fish was probably less than 83 for three consecutive years (2005 to 2007), there was precipitous decline, and the fall 2007 escapement was a catastrophe considering the spring 2005 wet year conditions." It identifies the Project's control of instream flow to be a significant limiting factor affecting natural salmon production: "The number of naturally produced adult salmon that return to the Tuolumne River is primarily a response of the juvenile salmon to the flows released at La Grange Dam during the winter and spring..."

In a request for rehearing letter written by DFG on May 5, 2008 to FERC, DFG wrote that neither ocean harvest, ocean conditions, nor Delta exports, even though they are in fact minor sources of mortality, are strong controlling factors in the abundance, health and vitality of the Tuolumne River adult salmon population. Annual adult salmon escapement abundance in the Tuolumne River began its sharp decline well before the poor ocean condition phenomena experienced in summer of 2007 (Figure 9, Page 16, Marston 2008). Additionally, a new analysis of the relationship between Delta smolt survival and Delta exports, and San Joaquin River inflow [i.e. Tuolumne River contributions along with other tributary flows (Newman 2008)] suggest that the Tuolumne River adult salmon population is

primarily affected and controlled by in-tributary limiting factors, rather than oceanic or other downstream controlling features.

As further described in the DFG letter written on May 5, 2008 to FERC, the primary factors controlling the salmon population to the Tuolumne River are occurring within the reach of the River which is directly operated in association with Project 2299. Districts have asserted that other downstream factors within the San Joaquin River and Delta are principally responsible for the observed salmon population declines. However, since Tuolumne River flow contributions from the Project requirements are important in determining the fate of salmon and other species (e.g., Delta smelt, longfin smelt, steelhead), in the Delta this, too, is a direct effect of Project operations. We have observed a very dramatic decline in Tuolumne River salmon adult escapement between 2000 and 2007, while the Fishery Settlement Agreement flow regimes and other protective features have been in place. The strong relationship between this observed population decline and the conditions of reduced spring flow and elevated spring water temperature indicated needed changes in the operations of Project 2299. Our analysis, only a part of which is provided above, shows fairly comprehensively that out-of-tributary limiting factors are indeed in play, yet are not the most important determinants of Tuolumne River salmon production, by at least an order-of-magnitude.

Alternatives to the WSIP

Accordingly, the WSIP draft PEIR identified the Modified WSIP Alternative as the environmentally superior alternative. This alternative implements all of the proposed WSIP projects, but would modify proposed system operations to minimize environmental effects. Modified proposed system operations to be considered as environmentally minimal must not include increased diversions from the Tuolumne River. Since there is strong evidence the Tuolumne River as managed, for the reasons discussed above and others, lacks sufficient water flows to keep in good condition anadromous salmonids, DFG does not agree with increased diversions from the Tuolumne River. Diversions of even 3-mgd of water from the Tuolumne River would be cumulatively considerable [see CCR Title 14, Section 15065(a)(3)] and put Chinook salmon at *high risk of extinction* in that watershed. Consequently, we continue to respectfully request SFPUC to use alternative water sources other than the Tuolumne River system to meet purchase requests in 2030 and drought year demands, at least until Project 2299 can properly address the inadequacies in the current flow regime for the purpose of creating, enhancing and supporting a sustainable anadromous fishery in the lower Tuolumne River.

DFG encourages SFPUC continue aggressive conservation and water recycling. Furthermore, year-round desalination at Oceanside to provide 25-mgd customer purchase requests through 2030 could be a good alternative for protecting salmonids of the Tuolumne River. With the implementation of alternative energy sources and proper brine disposal, such as dilute diffusion, the desalination alternative has the potential to be an environmentally superior alternative.

Comments on Biological Resources

California Annual Grassland, Pg. 4.6-1: California annual grassland is the predominant natural community at the Project sites. At the Tesla Portal site, there are approximately 42 acres of California annual grassland, and about 25.6 acres of annual grassland at the Thomas Shaft site. The proposed Project would result in the permanent loss of approximately 3.2 acres of California annual grassland at the Tesla Portal site. Permanent loss of California annual grasslands would contribute incrementally to the statewide loss of this type of habitat. As such, the impact of permanent loss of California annual grasslands from the proposed Project combined with the permanent loss of California annual grasslands of other projects identified in Table 4.15-a would be potentially significant (pgs. 4.15-13 and 4.15-14). Therefore, loss of California annual grassland at the Tesla site would contribute to a "cumulatively considerable" impact and substantially degrade the quality of the environment as stated in Section 15065 of the CEQA guidelines. Mitigation Measure 4.6-1a indicates participation in the San Joaquin Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) which includes compensation for the permanent loss of 0.308-acre of habitat values of artificial wetland, the temporary loss of <0.001-acre of ephemeral drainage, the temporary loss and permanent conversion of natural lands and incidental take authorization for special-status species. Participation in the SJMSCP should include, but not be limited to, 3.2 acres of permanent conversion of California annual grassland.

Special-Status Plant Species, Pg. 4.6-6: One special-status plant species, Mt. Diablo cottonweed, was observed along the access road leading to the Thomas Shaft site, but is not located within the Project footprint or construction staging area (Weiss Associates, 2003). During construction, the access road to the Thomas Shaft site should not be modified in any way which could impact Mt. Diablo cottonweed.

According to the May and Associates technical report on page 55 in the table titled "Plants Observed," both the Thomas Shaft and Tesla sites have known occurrences of *Amsinckia* spp. It is important a distinction is made which *Amsinckia* spp. is present since *Amsinckia grandiflora* is Federally- and State-listed as endangered, and has CNPS status 1B. *Amsinckia lunaris* also has CNPS status 1B. Until this distinction has been made, construction activities should be restricted.

Impacts on sensitive habitats, common habitats, and heritage trees (Tesla Portal: PSM; Thomas Shaft: LS, pg. 4.6-23): Temporary impacts resulting from construction staging and other construction-related activities at the Tesla Portal Project site would result in impacts to 11.716 acres of California annual grasslands, <0.001-acre of ephemeral drainage, and 0.846 acre of ruderal/disturbed habitat. Temporary impacts to California annual grasslands and aquatic habitat would contribute to the degradation of natural habitat in the region and could result in the potential permanent loss of habitat. Mitigation Measures 4.6-1a, 4.6-1b and 4.6-2 (participation in the SJMSCP, implement Best Management Practices and returning the site to pre-project conditions) would reduce potential temporary construction impacts to less than significant.

Since prior to the commencement of construction activities, the SFPUC will coordinate with the Joint Powers Authority/Technical Advisory Committee and pay necessary fees to fund offsite compensation under the terms of the SJMSCP, any temporary impacts that could result in the potential permanent loss of habitat should be considered as a permanent impacts.

Comments on Special Status Wildlife Species

Implement Incidental Take Minimization Measures for San Joaquin Kit Fox, Pg. 5-6:
A qualified biologist shall conduct preconstruction surveys 14 to 30 calendar days prior to commencement of ground disturbance. These surveys should be conducted no later than two weeks prior to commencement of ground disturbance.

Preconstruction surveys for the San Joaquin kit fox should adhere to the U. S. Fish and Wildlife Service's (USFWS) San Joaquin Kit Fox Survey Protocol for the Northern Range. Accordingly, DFG recognizes properly qualified biologists conducting San Joaquin kit fox surveys as described by the USFWS must have demonstrable experience in kit fox biology, identification and survey techniques.

Furthermore, DFG as described by the USFWS Standardized Recommendations for Protection of the San Joaquin Kit Fox Prior to or During Ground Disturbance (1999), does not consider water storage or conveyance facilities that promote urban growth or agriculture small projects. Recommendations for take minimization measures for San Joaquin kit fox should follow the above referenced document under the section "other projects."

Determine Burrowing Owl Presence

Breeding Season Surveys

The California Burrowing Owl Consortium (Consortium) survey protocol specifies a multi-phase approach, which is recommended in order to adequately evaluate burrowing owl use of an area and to inform the CEQA process. Phase 1 of the protocol begins with a habitat assessment that recognizes that burrows are the essential component of burrowing owl habitat and that burrowing owls may use man-made structures as burrows (see Page 1 of Consortium guidelines). If suitable habitat [appropriate vegetation and burrow(s) or burrow surrogate(s)] is present, then a Phase 2 intensive burrow survey is necessary even if owl sign is not present during the habitat assessment phase. Owl signs include molted feathers, cast pellets, prey remains, egg shell fragments, or excrement at or near burrow entrance or perch site. During the intensive burrow survey phase, burrow concentration areas should be mapped. Phase 3 of the protocol requires four survey visits whether or not owl sign is observed during Phase 2. DFG recommends that the Consortium survey protocol for breeding season surveys be adhered to [4 survey visits spread evenly (roughly every three weeks) during the peak of the breeding season, from April 15 to July 15] until enough information is available to warrant their revision or until new detailed protocols are developed as part the Conservation Strategy. The habitat assessment, intensive burrow surveys and burrowing owl surveys should include the area within 150 meters of the Project boundaries (approximately 500 feet).

Non-Breeding Season Surveys (Including Winter)

Surveys during the non-breeding season (September 1 to January 31) are recommended by DFG but are not generally required because burrowing owls are much more difficult to detect during the non-breeding season, and the number or type of surveys that would be needed to detect presence then has not been studied or quantified. Owls detected during non-breeding season surveys may be year-round residents or their young from the previous nesting season, pre-breeding territorial adults, winter residents, dispersing juveniles, migrants, or new colonizers. Negative results during any non-breeding season surveys are not conclusive proof that owls do not use the site. Because of this complication, DFG recommends breeding season surveys as the first step, but project applicants should consult with DFG if burrowing owls have been documented on the Project site during the non-breeding season.

Avoid Impacts (destruction, disturbance) to Individual Owls

Pre-Construction Surveys for Owl Presence

Pre-construction surveys (usually initiated during the non-breeding season) are necessary for assessing owl presence at a site within a short time period before site modification is scheduled to begin. Pre-construction surveys are supplemental to the existing breeding season survey protocol (four survey visits spread evenly during the peak of the breeding season, from April 15 to July 15), and should not be used in place of it without consulting with DFG in advance. The pre-construction surveys are intended to document if colonizing owls have recently moved onto the site, or if burrow locations of resident owls have changed, or if young of the year are still present and have not yet fledged or dispersed. Because any one or all of these events may have occurred on site since the breeding season (protocol) surveys were completed, it is important to also complete the pre-construction surveys in order to avoid direct take of owls or their nests and to design proper minimization and mitigation measures (e.g., document number and reproductive status of resident owls and location of satellite burrows, establish buffer zones and equipment/personnel travel routes and work/storage areas, unequivocally evict owls and ground squirrels from burrows).

Initial pre-construction surveys should be conducted outside of the owl breeding season (from February 1 to August 31) but as close as possible to the date that ground-disturbing activities will begin, to avoid the problem of waiting until March or April when the Project would be delayed if owls are detected. Generally, initial pre-construction surveys should be conducted no more than 30 days prior to ground-disturbing activities (i.e., disking, clearing, grubbing, grading). The time lapse between surveys and site disturbance should be as short as possible and will be determined by DFG based on specific project conditions but generally should not exceed seven days. Additional surveys are necessary when the initial disturbance is followed by periods of inactivity or the development is phased spatially and/or temporally over the Project area.

The number of pre-construction surveys necessary to accurately detect current owl presence and owl locations will be driven by a number of interacting criteria such as: 1) the time period that has elapsed since the last breeding survey was completed; 2) height and density of vegetation that may obscure owl presence; 3) topographical conditions that may

obscure owl presence; 4) time of year (e.g., in the winter owls are more cryptic and spend more time in their burrows); 5) time of day and weather conditions when surveys are conducted; 6) long-term history of owl use at the site; 7) size of the parcel and degree of coverage by walking or by intensive observations via spotting scope, and 8) tolerance of owls to human presence. Generally, at a minimum, four survey visits on at least four separate days will be necessary, especially given the cryptic nature of this species during the non-breeding season.

Biologists conducting pre-construction surveys should expend enough effort, based on the above criteria, to assure with a high degree of certainty that take of owls will not occur once site modification and grading activities begin. The full extent of pre-construction survey effort must be described and mapped in detail (e.g., dates, time periods, area(s) covered, and methods employed) in a biological report. Current vegetation and topographical conditions and their corresponding effect on visibility should also be described. The report should be submitted to DFG for review.

DFG's concurrence with the pre-construction survey results will depend on the level of detail that is provided in the Consultant's biological report that summarizes the methods, results, and level of survey effort. DFG has a responsibility to give input regarding measures that would result in avoiding take and minimizing unavoidable impacts to owls.

Take Avoidance

Avoidance of take of individual burrowing owls and their nests is currently mandated under Fish and Game Code sections 86, 3503, 3503.5 and 3513.

Burrows are an essential ecological requisite for burrowing owls throughout the year. Loss of nest burrows, satellite burrows, breeding concentrations, foraging habitat, dispersal and migration habitat, wintering habitat, habitat linkages and stepping stones, including habitat supporting host burrowers, and other essential habitat attributes, can individually or collectively have significant impacts on burrowing owls. DFG will work with Project proponents and lead agencies to develop compensatory mitigation for impacts to burrowing owls.

Conduct Pre-Construction Surveys for Swainson's Hawk, Pg. 5-8: A distance of two times the dripline of the tree is arbitrary and in the event any occupied nests are found, DFG will help determine appropriate actions based on scientific recommendations for construction activities. These measures may include waiting for the birds to fledge and forage on their own prior to construction or having a biological monitor on site to determine an appropriate buffer by monitoring any changes in behavior. If any Swainson's hawks are found nesting in the area, DFG should be notified to determine appropriate actions.

Implement Incidental Take Minimization Measures for White-Tailed Kite, Pg. 5-8: The white-tailed kite is a Fully-Protected species under Fish and Game Code Section 3511. Fully-Protected species may not be taken or possessed at any time and no licenses or permits may be issued for their take except for collecting these species for necessary scientific research. Therefore, the avoidance measures must prevent the take of these

species. If the species is found nesting, a setback from nesting areas shall be established far enough away to prevent any impacts. The buffer shall be maintained during the nesting season for the period encompassing nest building and continue until fledglings leave nests. If any white-tailed kites are found nesting, DFG should be notified to determine or confirm an appropriate buffer zone.

Implement Incidental Take Minimization Measures for California Horned Lark and Northern Harrier, Pg. 5-9: If species are found, a setback of 500 feet from nesting areas shall be established and maintained for the period encompassing nest building and continuing until fledglings leave nests, unless other measures are agreed to by DFG, or offsite compensation shall be provided. If any bird nests are found, DFG should be notified to determine or confirm the appropriate buffer zone for the species.

Conduct Pre-Construction Surveys for Golden Eagle, Pg. 5-9: Golden eagles are Fully-Protected under Fish and Game Code Section 3511. Fully-Protected species may not be taken or possessed at any time and no licenses or permits may be issued for their take except for collecting these species for necessary scientific research. Therefore, the avoidance measures must prevent the take of these species. If the species is found nesting, a setback from nesting areas shall be established far enough away to prevent any impacts. The buffer shall be maintained during the nesting season for the period encompassing nest building and continuing until fledglings leave nests. If any nests are discovered, DFG should be notified to determine appropriate actions.

Conduct Pre-Construction Surveys for Ferruginous Hawk and Prairie Falcon, Pg. 5-10: If species are found, a setback of 500 feet from nesting areas shall be established and maintained for the period encompassing nest building and continuing until fledglings leave nests, unless other measures are agreed to by DFG. If any bird nests are found, DFG should be notified to determine or confirm the appropriate buffer zone for the species.

We appreciate your consideration of our comments. If you have any questions, please contact Mr. Wes Stokes, Environmental Scientist, at (707) 944-5571 or wstokes@dfg.ca.gov; or Mr. Greg Martinelli, Water Conservation Supervisor, at (707) 944-5570.

Sincerely,

Charles Armor

10.3 Response to Comments from the Governor's Office of Planning and Research (S-OPR)

[S-OPR-01]

This letter acknowledges that the comment period for the Draft EIR closed on October 8, 2008. It also lists the reviewing agencies. Two agencies responded with comments: California Department of Transportation and California Department of Fish and Game. Responses to comments from these state agencies are addressed under responses to S-Caltrans and S-CDFG. The comment states that the San Francisco Planning Department has complied with the State Clearinghouse review requirements for draft environmental impact reports pursuant to the California Environmental Quality Act. No response is required.

The comment is noted for the record. No change to the Draft EIR is required.

Re: SFPUC San Joaquin Regional Water Quality Improvement Project

Dear Mr. Harrington:

The San Francisco Department of Public Health Environmental Health Section supports the water quality goals of the SFPUC San Joaquin Regional Water Quality Improvement Project as being consistent with public health protection.

Disinfection of drinking water is one of the most successful public health interventions; ultraviolet (UV) treatment is an advanced type of disinfection which can inactivate viruses, bacteria and protozoans that may be a source of illness. In particular, UV treatment will disinfect *Cryptosporidium*, a protozoan parasite that is resistant to the disinfection techniques currently in use in the SFPUC water system.

The project is imperative to SFPUC's ability to comply with regulations of the U.S. Environmental Protection Agency (EPA) under the Long Term 2 Enhanced Surface Water Treatment Rule. EPA promulgated these rules specifically to enhance protection of public health; they require improvements to drinking water disinfection and other treatment practices to ensure the public is best protected from risks posed by potentially waterborne infectious agents. Timely compliance with their requirements is crucial to realize these public health benefits. UV is an extremely effective strategy for SFPUC to comply with these regulations. [01]

The SFPUC San Joaquin Regional Water Quality Improvement Project will also have other public health benefits, including improved safety of chemical storage facilities, and improved seismic reliability.

Very truly yours,

June M. Weintraub, Sc.D.
Senior Epidemiologist

10.4 Response to Comments from the San Francisco Department of Public Health (L-SFDPH)

[L-SFDPH-01]

The commenter identifies some of the public health benefits of the project. The comments are noted for the record. No changes to the Draft EIR are required.

LANDMARKS PRESERVATION ADVISORY BOARD

1650 Mission Street, Suite 400 | San Francisco, CA 94103-2479 TEL: 415.575.6916 | FAX: 415.558.6409

October 3, 2008

Mr. Bill Wycko
Acting Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Wycko,

On Wednesday, September 17, 2008, the Landmarks Preservation Advisory Board (Board) held a public hearing and took public comment on the Draft Environmental Impact Report (DEIR) for the San Joaquin Regional Water Quality Improvement Project dated August 25, 2008. After discussion the Board arrived at the following comments listed below:

- The Board suggested that it would be helpful to have copies of the context statement for the water system to be use as a guide and/or tool for future projects. [01]
- On page 57, the Board supports and recommends the following comment regarding the steam engine foundations and bucket assembly: "*since they are closed to the staging area, it is recommended that they be properly fenced off to avoid potential inadvertent physical impacts or damage to the resource that could occur during project construction*". [02]
- On page 4.7.6 (DEIR), and on pages 27 and 28, a brief summary about the political controversy surrounding hydro-electric power should be included. The Board suggested strengthening that statement by providing recognition of the opposition by electrical power companies for constructing this facility, especially PG & E. [03]
- The Board appreciates the opportunity to provide their comments but does not feel comfortable commenting on the archeological components of the project because there is not an archeologist member of the Board. [04]

The Landmarks Preservation Advisory Board appreciates the opportunity to participate in the review of this environmental document.

Sincerely,

M. Bridget Maley, President
Landmarks Preservation Advisory Board

10.5 Response to Comments from the San Francisco Landmarks Preservation Advisory Board (L-SFLPAB)

[L-SFLPAB-01]

The commenter suggests that it would be helpful to have copies of the water system context statement for use as a guide/tool for future projects. The comment is noted for the record. No changes to the Draft EIR are required.

[L-SFLPAB-02]

The commenter requests that at the Thomas Shaft site, the steam engine foundations and bucket assembly areas be fenced during construction to avoid inadvertent impacts to the resource. The text on page 3-11 of the Draft EIR project description is revised to include fencing of the steam engine foundation and bucket assembly as follows:

> Other improvements proposed at the Thomas Shaft site include installation of a 360-square-foot prefabricated structure 10 feet in height within the fenced area atop Thomas Shaft and replacing two existing 100 horse power (hp) pumps with two 30 hp pumps (one active and one standby). A trench, approximately 150 foot by 3 foot by 3 foot would be excavated from the existing Chlorination Facility building to the Thomas Shaft and to the percolation tank (as shown on Figure 3-2). Prior to commencement of this project, fencing will be installed as part of another project (Thomas Shaft Roadway Improvement Project, SFPUC Resolution No. 08-0061) and will remain installed around the steam engine foundation and bucket assembly; this fence will avoid potential inadvertent physical impacts or damage to the resource that could occur during project construction.

[L-SFLPAB-03]

The commenter requests that additional information be provided in the Draft EIR regarding the historic political controversy surrounding hydroelectric power related to the Hetch Hetchy System. The text on page 4.7-6 of the Draft EIR is revised to include the following description of the history of hydroelectric power in the region as follows:

> The Sierra Club, along with San Joaquin Valley farmers and the Spring Valley Water Company, contested the damming of the Tuolumne River. Opposition to construction of the Hetch Hetchy project came from a variety of interests. Understandably, the Spring Valley Water Company opposed this project, which effectively ended its role as the utility company supplying San Francisco with its municipal and domestic water (SFPUC, 1949). The Hetch Hetchy project was designed to transmit electrical power to San Francisco from a power plant at Moccasin. A politically charged conflict over this electric power and associated revenue pitted public power advocates against the privately financed electric power industry. Opposition came from electrical power generating companies like Pacific Gas and Electric Company (PG&E) and Great Western Power

Company (GWP), two utilities that served San Francisco and the Bay Area at the time. These private power companies opposed the competing generation and sale of electricity by public agencies, which was a provision of the Raker Act. The City and County of San Francisco (CCSF) planned to acquire PG&E and GWP's distribution systems within its service area, but between 1927 and 1941 the public consistently rejected bond issues required to fund their acquisition; allegedly, this opposition to the bond measures was largely funded by PG&E (Hundley, 1992; Sayles, 1985). The CCSF's agreements to have PG&E (which had acquired GWP in the 1930s) wheel its power through the company's existing transmission and distribution systems for delivery to San Francisco agencies, and its purchase of city power for resale, caused a longstanding controversy between the federal government, public power advocates, and the CCSF.

The text on page 4.7-29 of the Draft EIR is also revised to include the following additional references:

Hundley, Norris, *The Great Thirst: Californians and Water*, 1770s–1990s. University of California Press, pp. 187–189, 1992.

SFPUC, *San Francisco Water and Power*, pp. 57–61, June 1949.

The text on page 4.7-30 of the Draft EIR is also revised to include the following reference:

SFPUC, Thomas Shaft Roadway Improvement Project, SFPUC Resolution No. 08-0061, April 8, 2008.

Sayles, Stephen P., Hetch Hetchy Reversed: A Rural Urban Struggle for Power. *California History*, 64:4, pp. 256, Fall 1985.

[L-SFLPAB-04]

The commenter states that the board appreciated the opportunity to issue comments about the project but does not have an archeologist on the board to comment on the archaeological components. The comment is noted for the record. No changes to the Draft EIR are required.

BAWSCA
Bay Area Water Supply & Conservation Agency

October 3, 2008

RECEIVED
OCT 06 2008
CITY & COUNTY OF S.F
PLANNING DEPARTMENT
M E A

Mr. Bill Wycko
Acting Environmental Review Officer
San Joaquin Regional Water Quality Improvement Project Draft EIR
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Subject: **Case No. 2007.0427E – San Joaquin Regional Water Quality Improvement Project Draft Environmental Impact Report**

Dear Mr. Wycko,

Thank you for the opportunity to provide the following comments from the Bay Area Water Supply & Conservation Agency (BAWSCA). BAWSCA represents the interests of 25 cities and water districts, an investor-owned utility, and a university, that purchase water wholesale from the San Francisco Regional Water System. These agencies, in turn, provide water to 1.7 million people, businesses and community organizations in Alameda, Santa Clara and San Mateo counties. These comments are in response to the Draft Environmental Impact Report (EIR) published August 25, 2008 for the San Joaquin Regional Water Quality Improvement project.

The comments below follow the report organization and do not reflect the level or priority.

1. **Section 2.12 – SFPUC Water System Improvement Program**
The footnote for Table 2-1 cites the January 2006 statement of level of service goals as presented in "San Francisco Public Utilities Commission, Water System Improvement Program" as the source for this table. The January 2006 document was clarified in a subsequent document which should also be referenced in the footnote and added to Section 2.5 – References. The source is "Parsons, WSIP System Assessment for Levels of Service Objectives; Prepared for San Francisco Public Utilities Commission, Final Report, November 22, 2006." [01]

2. **Section 3.3 – Proposed Project Components**
The new facility will significantly increase the power requirement for this site, however there appears no mention of what improvements may be required by PG&E to provide this power demand. UV systems are also sensitive to power interruptions. Please discuss the reliability of the power source to meet the new higher demand. [02]

3. **Section 3.7 – Approvals and Permits Required**
Please add the California Department of Public Health as one of the permitting agencies for this project. [03]

4. **Section 4.14 Energy Resources**
The energy consumption at the Tesla site is stated as increasing from 175,000 kWh per year to a new total of 6,000,000 kWh per year of which 3,550,000 kWh are for the UV generators. The power numbers quoted on page 4.14-6 appear to not add up since it is also stated that the UV reactors will require 1,800,000 kWh per year. Please verify the numbers and be sure they are consistent. Also, since the power use will go up nearly 10 times the current usages, what improvements will PG&E provide on their end? Are new transmission lines required? In the past, the Tesla Site appeared to have unstable power since it was near the end of the power grid. Since the power source is important given the sensitivity of UV reactors to stable power source, what is the large picture plan to ensure this reliability? [04]

Thank you for the opportunity to provide these comments on the Draft EIR for the San Joaquin Regional Water Quality Improvement Project dated August 25, 2008. If you have any questions, please contact me at (650) 349-3000.

Sincerely,

Nicole M. Sandkulla

10.6 Response to Comments from the Bay Area Water Supply & Conservation Agency (L-BAWSCA)

[L-BAWSCA-01]

The commenter requests that the reference to Table 2-1, WSIP Goals and Objectives, be updated to include an additional reference. Per SFPUC Resolution No. 08-0200, the WSIP was adopted on October 30, 2008 and as a result the Goals and Objectives were further refined. Therefore, the most current source for Table 2-1 is SFPUC Resolution No. 08-0200 and Table 2-1 has been modified accordingly. Please refer to Chapter 3 of this document, Staff-Initiated Text Changes, for the updates to Table 2-1.

[L-BAWSCA-02]

The commenter has requested a discussion of the reliability of the power source that would be used to meet the new electrical demand. SFPUC has consulted with PG&E regarding historic outages at the facility. The data provided by PG&E shows that some outages occurred prior to 1998. However, reliability has improved and the outages within the last 10 years have not been significant. Between 1995 and 2006, the average number of the sustained outages was three per year, averaging 95.6 minutes per outage (SFPUC, 2008). Momentary outages also averaged three per year during that period. The onsite power backup system is automatically activated for all power interruptions and momentary outages.

In addition, to ensure uninterrupted service, the Tesla Treatment Facility is designed to address reliability. As described on page 3-7 of the Draft EIR, the facility is designed for "zero failure," providing both backup ultraviolet (UV) reactors and backup power generators. In addition, power supply at the site is being upgraded to improve reliability and to minimize the potential for power outages. As further described on page 3-9 of the Draft EIR, a new electrical transformer will be provided on site as a part of the project and a new electrical transmission line will be extended from the existing power pole to the new transformer and then undergrounded to the new buildings. All of these measures are included to improve the capacity and reliability of electrical supply to the Tesla Treatment Facility. The SFPUC has submitted a Service Application to PG&E for their review, and PG&E does not expect the need for any major improvements.

[L-BAWSCA-03]

The commenter requests that the California Department of Public Health be added as one of the permitting agencies for the project. In response to this comment, the following text on page 3-21 of the Draft EIR has been added as follows:

- Modification to Regional Operational Permit will be issued by the California Department of Public Health for changes in disinfection equipment used (Tesla Portal and Thomas Shaft sites).

[L-BAWSCA-04]

The commenter requested clarification of the anticipated energy consumption for the project facility. The estimated energy consumption described on page 4.14-6 of the Draft EIR for the new facilities at the Tesla Treatment Facility is accurate. The total energy consumption at the

Tesla Portal site would increase to a total estimated usage of 6,000,000 kilowatt-hours (kWh) per year. The existing Tesla Portal Hypochlorite Station, which uses most of the existing power at the Tesla Portal site (175,000 kWh), would be replaced by new facilities. Therefore, the energy consumption estimate for operation of the new facilities at the Tesla Portal site includes 1,800,000 kWh for the three buildings, 3,550,000 kWh for the UV reactors and approximately 650,000 kWh for the pumps, for a total of 6,000,000 kWh per year. Although no changes to the Draft EIR are required, page 4.14-6 of the Draft EIR has been revised to provide further clarification:

> SFPUC Power Enterprise provides power to the SFPUC's regional water system facilities, which use an estimated total energy usage of approximately 44 million kWh per year. This annual estimate includes the Tesla Portal facilities, which has a current demand of approximately 175,000 kWh per year. Operation of the new facilities at the Tesla Portal site could substantially increase overall on-site energy consumption. The SFPUC estimates that, in total, operation of the proposed improvements at the Tesla Portal facility would require approximately six million kWh per year. This estimate includes approximately 1,800,000 kWh for operation of the three new buildings (UV building, Chemical Process building and Office/Control building), approximately 3,550,000 kWh for the UV reactors, and approximately 650,000 kWh for the proposed pumps). Accounting for current energy use ~~This additional energy demand~~ at the Tesla Portal site ~~would~~, the project would result in a net increase of approximately 5,825,000 kWh, which represents roughly 13 percent of the regional water system's current annual energy use. ~~Under the significance criterion for energy, this additional energy demand represents the use of a large amount of energy, which is considered a potentially significant impact.~~ As described in the setting, the energy use by the regional water system is a fraction (less than three percent) of the long-term annual average energy production of the Hetch Hetchy system, and would remain at approximately three percent including the project's increased operational energy use.

Please see response to comment L-BAWSCA-02 for a discussion of power delivery and reliability.

San Joaquin Valley
AIR POLLUTION CONTROL DISTRICT

October 6, 2008

Bill Wycko
San Joaquin Regional Water Quality Improvement Project EIR
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Project: Case No. 2007.0427E San Joaquin Regional Water Quality Improvement Project

District Reference No: 20080582

Dear Mr. Wycko,

The San Joaquin Valley Unified Air Pollution Control District (District) has reviewed the project referenced above and is providing the following comments:

1. As indicated in the draft Environmental Impact Report (EIR), the proposed project would be subject to District Rule 9510 (Indirect Source Review) because upon full build-out the project would include or exceed 9,000 square feet of space.

   District Rule 9510 is intended to mitigate a project's impact on air quality through project design elements or by payment of applicable off-site mitigation fees. Any applicant subject to District Rule 9510 is required to submit an Air Impact Assessment (AIA) application to the District no later than seeking final discretionary approval, and to pay any applicable off-site mitigation fees before issuance of the first building permit. If approval of the subject project constitutes the last discretionary approval by your agency, the District recommends that demonstration of compliance with District Rule 9510, including payment of all applicable fees, be made a condition of the project's approval. [01]

   Information about how to comply with District Rule 9510 can be found online at: http://www.valleyair.org/ISR/ISRHome.htm.

2. As previously stated in our comment letter dated June 19, 2007, the EIR should include estimates of projected pollutant emissions related to the project, and the methodology, model assumptions, inputs and results. The EIR should identify the components and phases of the project. The EIR should provide emissions projections for the project at the build out of each phase (including ongoing [02]

10.7 Response to Comments from the San Joaquin Valley Air Pollution Control District (L-SJVAPCD)

[L-SJVAPCD-01]

The commenter is reiterating that the proposed project would be subject to San Joaquin Valley Air Pollution Control District (SJVAPCD or District) Rule 9510 (Indirect Source Review). As described under Impact 4.9-1, Construction Emissions of Criteria Pollutants, on p. 4.9-22 of the Draft EIR, the project would be subject to the requirements of Rule 9510. Accordingly, NO_x and PM_{10} reduction measures will be implemented for the SJRWQIP through Mitigation Measure 4.9-1a, SJVAPCD Dust Control Measures and Mitigation Measure 4.9-1b, SJVAPCD Exhaust Control Measures. As described further in response to comment L-SJVAPCD-02, below, implementation of these measures will achieve onsite reductions required by District Rule 9510. Prior to commencement of construction of the SJRWQIP, the SFPUC will submit an Air Impact Assessment application to the SJVAPCD in accordance with Rule 9510. The proposed facility improvements at the Thomas Shaft would not be subject to Rule 9510 because the proposed project's square footage is well-below the SJVAPCD's applicability threshold and construction emissions are considered minor.

[L-SJVAPCD-02]

The commenter requests that the Draft EIR include estimates of projected pollutant emissions for the various phases of the project.

CONSTRUCTION

Construction emissions have been estimated for the facility improvements at the Tesla Portal site and include construction of the chemical process building (14,000 square feet), the office/control building (3,500 square feet), and the UV building (20,000 square feet). Buildout at the Thomas Shaft site would result in a 360-square-foot prefab structure. The square footage of this structure is significantly below the SJVAPCD's 9,000-square-foot threshold for Rule 9510 (Indirect Source Review) applicability. For this reason construction emissions were only calculated for construction associated with the Tesla Portal site. Per the SJVAPCD's suggestion, URBEMIS was used to estimate unmitigated emissions. Table 4.9-5 below presents the results of these calculations.

URBEMIS was also used to calculate specific emission reductions to demonstrate compliance with District Rule 9510. Only the fugitive dust control measures specified in Mitigation Measure 4.9-1a of the Draft EIR were applied to the URBEMIS model as these were the only proposed mitigation measures that could be quantified in URBEMIS. Therefore, the application of all mitigation described in Mitigation Measures 4.9-1a and 4.9-1b would be expected to achieve even greater reductions. Unmitigated construction emissions of PM_{10} are below the District's Rule 9510 threshold of 2 tons/year and implementation of fugitive dust control measures would further reduce the PM_{10} dust emissions by approximately 40 percent. Rule 9510 also requires that NO_x emissions be reduced by 20 percent during construction. Mitigation Measure 4.9-1b also includes a host of measures that will be implemented to reduce exhaust emissions (including NO_x). As stated in Mitigation Measure 4.9-1b, construction equipment engines greater than 50 horsepower will be equipped with Tier 2

diesel engines. Equipment with Tier 2 diesel engines have resulted in tailpipe reductions of 21 to 39 percent for NO_x and 41 to 61 percent for PM (CARB, 2007). Therefore, implementation of this mitigation measure is expected to reduce NO_x emissions from construction significantly and exceed the District Rule 9510 reduction requirements.

Text of the Draft EIR has been revised to include more detailed construction emissions information as follows:

On page 4.9-22 of the Draft EIR, the following text and table are inserted in the first full paragraph:

> Equipment exhaust emissions are generated from the combustion of fuels used for the operation of construction equipment. Fugitive dust emissions are generated by the suspension of particulate during earth-moving activities. Employee vehicle emissions and construction truck emissions are generated from the combustion of fuels and from the entrainment of road dust during travel along roadways on site and off site of the construction area. Asphalt paving emissions are generated from the evaporation of regulated volatiles, or diluents, used to liquefy asphalt cement. Reasonable worst-case uncontrolled construction emissions are summarized in Table 4.9-5.

TABLE 4.9-5
REASONABLE WORST-CASE ANNUAL UNCONTROLLED EMISSIONS AT THE TESLA PORTAL SITE DURING CONSTRUCTION
(TONS PER YEAR)

Project Component	ROG	NO_x	CO	SO_2	PM_{10} (Dust)	PM_{10} (Exhaust)	PM_{10} Total	$PM_{2.5}$ (Dust)	$PM_{2.5}$ (Exhaust)	$PM_{2.5}$ Total	CO_2
Chemical Building	0.30	1.14	0.72	0	0.02	0.07	0.09	0	0.06	0.07	113.04
Office Building	0.18	1.06	0.57	0	0	0.07	0.07	0	0.06	0.06	94.04
UV Building	0.37	1.19	0.81	0	0.02	0.07	0.09	0	0.07	0.07	123.90
Total	**0.85**	**3.38**	**2.10**	**0**	**0.04**	**0.21**	**0.25**	**0.01**	**0.19**	**0.20**	**330.97**

Source: URS, 2008.

On page 4.9-23, the tenth paragraph under Impact 4.9-1: Construction emissions of criteria pollutants, is edited as follows:

> In accordance with the guidance outlined in the GAMAQI, the SFPUC would implement Mitigation Measures 4.9-1a and 4.9-1b, which require a host of actions that the SJVAPCD has determined will reduce fugitive dust (PM) emissions and equipment exhaust emissions. These measures include, but are not limited to: stabilization of dust emissions, hauling restrictions, track out restrictions, speed restrictions, idling restrictions, and activity management. See Section 5.2.5 for a

specific listing of these actions. Implementation of fugitive dust control measures alone would result in a reduction in PM_{10} dust-related emissions by 40 percent and $PM_{2.5}$ emissions by 38 percent. Total PM_{10} and $PM_{2.5}$ emissions would be reduced by 7 and 2 percent, respectively.) related to construction emissions at the Tesla Portal site (URS, 2008). Implementation of ~~these mitigation~~ all of the measures included in Mitigation Measures 4.9-1a and 4.9-1b would reduce the potentially significant air quality impact associated with project construction emissions of criteria pollutants at the Tesla Portal site to less than significant.

On page 4.9-23 of the Draft EIR, after the first paragraph under the title Thomas Shaft, the following paragraph has been modified as follows:

Details regarding the size, scope, and length of construction for the Thomas Shaft site are outlined in the project description (Chapter 3). Chapter 3 also details expected construction equipment that will be operational throughout build out. In general, construction at this location is anticipated to start July 2009 and last for approximately 6 months. The development footprint at the Thomas Shaft site is below the SJVAPCD's Rule 9510 threshold triggering the need for quantification and therefore emissions have not been calculated but are discussed qualitatively.

OPERATION

As stated in the Draft EIR, Section 4.9 Air Quality, Impact 4.9-3, operational emissions from the proposed project are considered to be minor, including emergency generators, diesel tank emissions, employee vehicle trips, and maintenance visits and deliveries at the Tesla Portal site. As described in the Draft EIR on page 4.9-20, project operation at the Thomas Shaft site would not require an emergency generator, diesel tanks, nor result in any increase in the number of employees required onsite and therefore would not result in any operational emissions. At the Tesla Portal site, the employee trips would be two vehicle round trips per day and deliveries and maintenance visits would be five round-trips per day. It was assumed employee and delivery trips would be coming from Tracy. The generators are assumed to be two 2,011-horsepower generators operating one hour per week for routine testing and emergency backup. As shown in Table 2.7-1, estimated emissions would not exceed the 2 tons/year threshold for NO_x or PM_{10}, which exempts operational emissions from District Rule 9510.

Text of the Draft EIR has been revised to include more detailed operations emissions information as follows:

On page 4.9-27 of the Draft EIR, the following text and table are inserted in the first full paragraph:

All operational exhaust emissions are generated from the combustion of fuels. Diesel tank emissions are generated from the displacement of volatile vapors

during refilling and the evaporation of volatiles. Reasonable worst-case uncontrolled operations emissions are summarized in Table 4.9-6.

Table 4.9-6
REASONABLE WORST-CASE ANNUAL UNCONTROLLED EMISSIONS ESTIMATES AT THE TESLA PORTAL SITE DURING OPERATIONS (TONS PER YEAR)

Subject San Joaquin Regional Water Quality Improvement Project: Draft EIR comment

1. From the descriptions of the Tesla and Lawrence-Livermore projects, it appears that the latter addresses giardia while the former does not. The same water is utilized. Is giardia addressed or to be addressed downstream of Tesla Treatment Facility? Is there a reason why one project addresses giardia while the other does not? [01]

2. PG&E power needs will increase. Why can't Hetchy hydropower power be used when available? By using Hetchy hydropower, cost for electricity would be lowered and clean energy would be used, lowering impact on greenhouse gas emission. [02]

Steve Lawrence

10.8 Response to Comments from Steve Lawrence (C-Lawre)

[C-Lawre-01]

The commenter states that it appears that the proposed project at Tesla Portal site does not address *Giardia*. The SFPUC water source is in compliance with the current Surface Water Treatment Rule, which requires *Giardia* inactivation. *Giardia* inactivation is currently accomplished through the addition of chlorine to the regional water supply at the Tesla Disinfection Facility, or at Thomas Shaft, if disinfection does not occur at Tesla. The addition of chlorine at these facilities provides for adequate contact time for the regional water supply to inactivate *Giardia*. This process would continue, unchanged, with implementation of the proposed project.

The new Long Term 2 Surface Water Treatment Rule requires that an unfiltered supply use two different disinfectants to inactivate three organisms: *Cryptosporidium*, *Giardia*, and viruses. For the proposed project, the two disinfectants would be ultraviolet light and chlorine.

In addition to providing for disinfection of the regional water supply, the Thomas Shaft facility also serves as the supply point for Lawrence Livermore National Laboratory (LLNL) Site 300. Since there is not sufficient contact time between the Tesla Treatment Facility and the Thomas Shaft site during certain periods to adequately treat the LLNL Site 300 water supply, the proposed project activities at the Thomas Shaft site (installation of a small UV unit) would ensure that *Giardia* inactivation for the water supply serving LLNL Site 300 can be achieved in accordance with the Surface Water Treatment Rule. The proposed project would therefore allow the SFPUC to satisfy their contractual agreement with LLNL to provide potable water to LLNL Site 300.

The following text on page 3-7 of the Draft EIR has been added as follows:

> *Giardia* inactivation is currently accomplished through the addition of sodium hypochlorite (chlorine) to the regional water supply at the Tesla Disinfection Facility or at Thomas Shaft, which provides adequate contact time for the inactivation of *Giardia*. To provide adequate *Giardia* disinfection to LLNL Site 300, additional ultraviolet (UV) facilities would be installed at Thomas Shaft (see Section 3.2). ~~Sodium hypochlorite~~ Chlorine would be fed from the Chemical Process Building and injected into the out flow manifolds. Although the location of the chlorination function at the site would change, the chlorine injection process itself would be essentially unchanged. In addition, to lower the pH of the water, fluoride and CO_2 would be added to improve current water quality management capabilities.

[C-Lawre-02]

The commenter states that the need for PG&E power will increase and questions why Hetch Hetchy hydropower is not used. As stated in the Draft EIR on pp. 4.11-4 and 4.14-2, SFPUC

Power Enterprise hydroelectric power is used to power the existing facilities at the Tesla Portal site and will continue to be used to power the new Tesla Treatment Facility. The City and County of San Francisco has an interconnection agreement in place with PG&E where SFPUC Power Enterprise hydroelectric power is distributed through PG&E's transmission lines. The City and County of San Francisco pays PG&E a per kWh charge to transmit SFPUC Power Enterprise hydroelectric power.

Bill Wycko, Environmental Review Officer
San Joaquin Regional Water Quality Improvement Project
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Wycko:

I am the Business Agent for the Plasterer's & Cement Masons Local 300, Area 429 representing skilled trades people from the Central Valley. I also serve on the San Francisco Public Utilities Commission (SFPUC) Water System Improvement Program (WSIP) Small Firm Advisory Committee, which assists the SFPUC in providing business opportunities to small, locally based construction companies throughout its service territory. I am writing to express our members' strong support for SFPUC's proposed San Joaquin Regional Water Quality Improvement Project.

We have closely monitored the SFPUC's progress, particularly in the Central Valley, during the development and initial construction of the WSIP, and the San Joaquin Regional Water Quality Improvement Project is especially important for all of our members who live and work in the area. The Tesla Treatment Facility Project and the Lawrence Livermore Water Quality Improvements will ensure that water provided by the Hetch Hetchy System continues to be of the highest quality for years to come. [01]

As a member of the SFPUC WSIP Small Firm Advisory Committee, I assure you that the SFPUC' is committed to utilizing local workers and contractors on this project. The construction of this treatment plant will provide many local residents with work opportunities.

In closing, I strongly urge to approve this project. If you have any questions, please do not hesitate to contact me.

Sincerely,

Lucille Palmer-Byrd
Business Agent, OPCMIA Local #300/Area #429

Cc: Steven Scott, Business Manager/Financial Secretary, OPCMIA Local 300

10.9 Response to Comments from the Plasterers' and Cement Masons' Local Union (G-OPCMIA)

[G-OPCMIA-01]

The commenter strongly urges that the project be approved. The comment is noted for the record. No change to the Draft EIR is required.

SPEAKERS:

JAMIE DEAN, San Francisco Planning Department

DAVID J. REEL, URS Corporation

BIJAN AHMADZADEH, San Francisco PUC

DAVID THOMAS, San Joaquin Building Trades

AUGIE BELTRAN, Carpenters Union Local 25

--oOo--

MS. DEAN: Okay. Good evening and welcome to today's public hearing on the draft environmental impact report for the San Joaquin Regional Water Quality Improvement Project. Please help yourself to refreshments over to my left, and the rest rooms are behind you.

My name is Jamie Dean. And I'm the environmental planner with the San Francisco Planning Department major environmental analysis section, and I will be leading this evening's meeting.

The first item on tonight's agenda is introductions, and then we will go through a project overview provided by the Public Utilities Commission. And then we'll open the hearing for public comments.

As I said, my name is Jamie Dean. I'm with the San Francisco Planning Department, and the San Francisco Planning Department is the lead agency under the

California Environmental Quality Act, also referred to as CEQA. The San Francisco Planning Department is the lead agency for all projects sponsored by the City and County of San Francisco.

As I said, the SFPUC is the project proponent, and with us here this evening is Bijan Ahmadzadeh, who's the project manager; Karen Frye, who's the environmental project manager; and Jim Marks with the communications department.

I would now like to turn this over to Bijan who will go through the project overview.

MR. AHMADZADEH: Good evening, everyone. My name is Bijan Ahmadzadeh. I'm the project manager for these two projects. So I guess we'll start out, just want to run through real quickly the project location. This is our Hetch Hetchy water system map. And the two projects that we're going to talk about real briefly tonight is the Tesla Portal site, which is just out on the other side of the golf club -- golf course, and the Thomas Shaft site which is about -- it's off of Corral Hollow Road about a mile away from here.

Okay. Our proposed project is part of the water system improvement program, and our goals pretty much follow the water system improvement goals which is basically maintaining high-quality water, reducing

vulnerability to earthquakes, increasing the water delivery reliability, meeting customer water supply needs, enhancing sustainability, and achieving a cost-effective, fully operational system.

Next slide. This is a little close-up view of the two locations. The Tesla Portal site, and the Thomas Shaft site is just outside of Tracy. And basically our existing Tesla Portal facility is 70 years old. It's the primary disinfection point for the Hetch Hetchy water system which we currently treat with sodium hypochlorite. And the existing facility is not built to current earthquake standards.

Next slide. The project objective for the Tesla treatment facility is basically replacing the existing facilities to meet current seismic safety, fire, and building code standards. Also the other objective of the project is to construct water treatment facilities to meet the new United States Environmental Protection Agency's regulation for inactivation of Cryptosporidium in drinking water.

Basically what this says, this rule says, is that we need to utilize two disinfection processes for treating water. One of them is going to be the advance disinfection, which basically the water going through an array of ultraviolet lights to kill pathogens. The other

disinfection is through the process of sodium hypochlorite which we currently are using.

And also the other object is improved water quality management capabilities. Basically adding fluoride and carbon dioxide to help do some adjustments to the pH of the water.

The Tesla site, which is a bigger picture here, is basically the objective of -- we have the existing San Joaquin -- three San Joaquin pipelines that are coming into the -- this parcel which is owned by the San Francisco PUC. It's a 54-acre parcel. We're going to be intercepting the three San Joaquin pipelines, and then on both upstream and downstream of this new facility.

And the site basically is going to be composed of the new disinfection process which is the UV building, a chemical process building, and also this admin building for our operators.

And then we'll -- the staging area for the construction site is going to be within this cross-hatched area and this cross-hatched area of the parcel. And then we'll have some road improvements to the new facility.

The other site is the Thomas Shaft facility site. Basically this site is our backup chlorination facility in case for some reason the sodium hypochlorite facility goes down, we have a backup facility at Thomas Shaft as backup.

And basically this is our delivery point to our -- one of our delivery points to our current -- well, our customer, to Lawrence Livermore National Laboratory.

Next slide. And the objectives for this project, similar to Tesla, is basically construction of water treatment facilities to meet the United States Environmental Protection Agency requirements for reduction of Cryptosporidium and Giardia, and also to enable delivery of potable water to Lawrence Livermore National Laboratory, which we have a contractual agreement with them to continue providing water to them. And also to be -- it will also continue to provide the backup chlorination capabilities as currently it is.

The Thomas Shaft site, this site is about one and a half miles off of Corral Hollow Road. There's an existing dirt road that we currently use to get up to the site. The UV facility -- the UV equipment is going to be housed within the existing chlorination facility. We'll have some pipe work connecting the existing treatment facility to some well heads that we -- currently is located just across the street from there.

And then we'll have some -- a small percolation tank for treating some of the processed water that comes from the process. And then we're proposing to construct a prefabricated building to protect the exposed

appurtenances over the well heads. And then we have some staging area just at the location of the facility. So those are the big picture overviews of the two projects. And so --

MS. DEAN: Okay. Thank you. So now onto this evening's public hearing. So the purpose of the meeting here tonight is to hear your comments on the accuracy and adequacy of the draft environmental impact report. And we will not be answering your questions here today, but rather your comments will be responded to in a comments and responses document.

So this is where you can submit written comments. You can hand them to me this evening. You can also participate in our next public hearing which will be before the San Francisco Planning Commission on Thursday. And you can also send by e-mail or fax or U.S. mail. And as a reminder, we will accept written comments and verbal comments until October 8th. That is the close of the public comment period.

If you would like to view the draft environmental report in its entirety, it's available on-line or also in print at the San Francisco Planning Department San Francisco main library and the Tracy library.

Okay. I'd like to go over some ground rules for this evening's comment period.

MR. REEL: Sorry about that, Jamie. Something happened.

MS. DEAN: That's okay.

MR. REEL: It's skipping that.

MS. DEAN: Well, the first is please complete any speaker cards. Those are on the table when you came in. And I will call your name, and if you could please just stand up and speak your points. We ask that you do keep it to a time limit of three minutes typically, but given that there are not a whole lot of us here, you can extend it to five minutes if you'd like.

You can also submit verbal comments directly to our court reporter if you are uncomfortable speaking to all of us. Okay. So with that --

MR. REEL: Did you want to call the two?

MS. DEAN: Sure. And with that, I'll get started. David Thomas.

MR. THOMAS: Where do I go to speak?

MR. REEL: I think if you're in front of the court reporter, then she can take your -- it will be easier to hear.

MS. DEAN: Yeah.

MR. THOMAS: Okay. Good evening. My name is Dave Thomas, and I'm with the San Joaquin Building Trades Council. And I'm here tonight to speak in favor of the [G-SJBTC-01]

project. I've been to many meetings regarding the Hetch Hetchy project, and this is a greatly needed facility here for the treatment of water for San Francisco. And it's going to be greatly needed in the area for jobs in the near future hopefully that's going to be starting pretty soon.

And I can speak on behalf of the Stanislaus Building Trades Council also who is in favor of this project, and there is another speaker here that will reiterate my comments. But we're in favor of it. And it's been EIR'd to death, I'm sure, and we have no reason to believe that there's anything wrong with the environmental impact reports. And San Francisco is a very conscientious county when it comes to construction and building.

And I just want to end my comments by saying we're in favor of the project and let's build it. Thank you.

[G-SJBTC-01] cont.

MS. DEAN: Okay. Augie Beltran.

MR. BELTRAN: Good evening. My name is Augie Beltran. I represent the Carpenters Union in the Central Valley. We've reviewed the EIR, and I think that since there are not a lot of people here, it's pretty much a testament to the work that is done over by you people over in San Francisco.

[G-CVCU-01]

You guys have done a great job of educating our public officials, educating our local citizens in letting them know that this is a good project. Anything that San Francisco puts their name on has got to be quality because you guys inspect the heck out of everything. [G-CVCU-01] cont.

So just know that the trades are behind you guys 100 percent. We fully endorse this EIR and we're here to help in any way. Thank you.

MS. DEAN: Okay. Is there anyone else that would like to speak? Okay. Well, I guess with that we can close the comment period for this evening. Can we put up the slide with where they can send additional comments? Okay.

MR. BELTRAN: You guys are lucky. Our plan took six hours in public hearing with 150 people.

MR. AHMADZADEH: So there's some billboards here, so if you have any more questions on these, on these pictures or some clarification, we'd be more than welcome to answer them.

(Time noted: 6:57 PM.)

SAN FRANCISCO PLANNING COMMISSION

Regular Meeting

Thursday, September 18, 2008

Agenda Item 12, 2007.0427E,

San Joaquin Regional Water Quality Improvement Project

Presentation and Public Comment

on the Draft Environmental Impact Report

City Hall, Room 400

Dr. Carlton B. Goodlett Place

San Francisco, CA 94102

Reported by: Freddie Reppond

A P P E A R A N C E S

FOR THE PLANNING COMMISSION:

Commissioner Christina R. Olague, President

Linda D. Avery, Commission Secretary

Commissioner Michael J. Antonini

Commissioner Gwyneth Borden

Commissioner William L. Lee

Commissioner Kathrin Moore

Commissioner Hisashi Sugaya

FOR THE SAN FRANCISCO PLANNING DEPARTMENT:

Jamie Dean, EIR Coordinator

--oOo--

[The item was called at 6:12 p.m.]

COMMISSION SECRETARY AVERY: This is Case No. 2007.0427. This is the San Joaquin Regional Water Quality Improvement Project.

COMMISSIONER SUGAYA: I would like to say, though, that we did -- Carey and Company did work on a related project on the -- not this San Joaquin but a different San Joaquin. And the report that we contributed to is referenced in the document, but I have no direct conflicts of interest, so I'm going to participate.

COMMISSION PRESIDENT OLAGUE: Thank you.

MS. DEAN: Good evening, President Olague and members of the Commission. My name is Jamie Dean and I'm with the major environmental analysis section of the Planning Department. I'm the EIR coordinator for the San Joaquin Regional Water Quality Improvement project. This project is sponsored by the SFPUC and it is one of the many facility-improvement projects that comprise the larger water-system-improvement program.

A programmatic EIR was prepared by the Planning Department on this larger program and published in June 2007. A responses-and-comments document for this program will be published at the end of September.

With me here today are some members of the

PUC, should you have any questions on the proposed project description.

COMMISSION PRESIDENT OLAGUE: Thank you.

At this time, we will open it up for comments on the EIR.

Is there any public comment on this item?

Seeing none, public comment is closed.

Commissioners?

COMMISSIONER LEE: There's no action --

COMMISSION PRESIDENT OLAGUE: No action required, but do we have comments? I'm not asking if you have action. I'm asking if you have comments.

COMMISSIONER SUGAYA: No. The cultural resources section is really great.

COMMISSION PRESIDENT OLAGUE: Okay. There we are. So thank you. There's no public comment. The Commissioners have no comments, other than Commissioner Sugaya's, so we are --

COMMISSION SECRETARY AVERY: Madam President, I would read into the record that written comments will be accepted at the Planning Department's offices until the close of business on October 8th, 2008.

With that, this item has been concluded. Thank you.

CHAPTER 3
Staff-Initiated Text Changes

3.1 Introduction

The following changes to the text of the San Joaquin Regional Water Quality Improvement Project (SJRWQIP, or proposed project) Draft Environmental Impact Report (Draft EIR) are made in response to comments on the Draft EIR, and to reflect changes made in the Water System Improvement Program (WSIP) Program EIR (PEIR) and the approval of the WSIP, or are included to clarify the Draft EIR text. The text revisions are organized by page number (or the first page number if there is more than one) that appears in the Draft EIR. In each change, new language is double underlined, while deleted text is shown in ~~strike-out~~.

3.2 Water System Improvement Program

As discussed in the Draft EIR, the SJRWQIP is part of the San Francisco Public Utilities Commission's (SFPUC) WSIP. The San Francisco Planning Department prepared a Draft PEIR on the WSIP, which was published in June 2007. Information on the originally proposed WSIP, as described in the Draft PEIR, was presented in the SJRWQIP Draft EIR. In response to comments on the Draft PEIR, the SFPUC proposed several changes to the WSIP. These changes are detailed in the Final PEIR along with the environmental effects of the revised program. The Final PEIR was certified by the San Francisco Planning Commission on October 30, 2008 (Motion No. 17734) and the revised WSIP (known as the "Phased WSIP Variant" in the Final PEIR) was adopted by the SFPUC (Resolution No. 08-0200) on the same day.

This chapter includes revisions to the SJRWQIP Draft EIR to account for the changes that were made to the WSIP subsequent to publication of the Draft EIR on the SJRWQIP, certification of the Final PEIR on the WSIP, and adoption of the WSIP by the SFPUC. Appendix B.4, B.5, and B.6 supplements this chapter by including the actual text from the Final PEIR on the revised WSIP along with other information from the Final PEIR that is relevant to the revised WSIP, such as its environmental effects.

3.3 Text Revisions

Table of Contents

Page v of the Draft EIR, Table of Contents, under Appendices the text is edited as follows:

A. NOP and Scoping Summary Report ~~(Provided on CD)~~ A-1
B. WSIP ~~Draft~~ PEIR Reference Chapters (Provided on CD) B-1
B.1 WSIP ~~Draft~~ PEIR Chapter 5 – Water Supply and System Operation-Setting and Impacts

B.2 WSIP ~~Draft~~ PEIR Chapter 7 – Growth Inducement Potential and Indirect Effects of Growth
B.3 WSIP ~~Draft~~ PEIR Chapter 9 – CEQA Alternatives
B.4 WSIP PEIR Revisions
B.~~4~~5 WSIP Draft PEIR Appendix E – Growth Inducement and Supporting Information
B.6 WSIP Draft PEIR Appendix O – Hydrologic Modeling – Additional Supporting Information

Page vi of the Draft EIR, Table of Contents, under List of Tables the following text is added per comment L-SJVAPCD-02:

Table 4.9-5 Reasonable Worst-Case Annual Uncontrolled Emissions at the Tesla Portal Site during Construction (Tons per Year)
Table 4.9-6 Reasonable Worst-Case Annual Uncontrolled Emissions at the Tesla Portal Site during Operation (Tons per Year)

Chapter 1 Executive Summary

Page 1-4 of the Draft EIR under 1.3 Summary of the Environmental Impacts and Mitigation the second paragraph has been changed as follows:

> As discussed in Chapter 6, Growth Inducement, the proposed project is one of several improvement projects that comprise the SFPUC's Water System Improvement Program (known as the "Phased WSIP Variant"), and implementation of the WSIP would support growth in the SFPUC service area, thereby contributing indirectly, to environmental impacts caused by that growth. Because the proposed project is part of the WSIP and would contribute to the WSIP's growth inducement impact, the project therefore would contribute to the potentially significant and unavoidable program-level impacts associated with growth inducement.

Page 1-5 of the Draft EIR under "1.6 Overview of SFPUC Regional Water System" the following paragraphs have been changed as follows:

1.6 Overview of SFPUC Regional Water System

The proposed project is a component of the SFPUC's ~~Water System Improvement Program (~~WSIP~~)~~. As a component of the WSIP, it contributes to the impacts that the WSIP, as a program, may have on the environment. To address the potential environmental impacts of the proposed WSIP, the San Francisco Planning Department prepared ~~published~~ a ~~Draft~~ Program EIR (~~Draft~~ PEIR) ~~on June 29, 2007~~that was certified by the San Francisco Planning Commission on October 30, 2008 (Motion No. 17734). At a project-level of detail, the ~~Draft~~ PEIR evaluated~~s~~ the environmental impacts of the WSIP~~SFPUC's proposed water supply option~~ and, at a program-level of detail, it evaluated~~s~~ the environmental impacts of the WSIP's facility improvement

projects. This section provides background on the SFPUC's water system, and the following sections provide background on the ~~proposed~~ WSIP and the ~~WSIP Draft~~ PEIR.

The CCSF, through the SFPUC, owns and operates a regional water system that extends from the Sierra Nevada to San Francisco and serves retail and wholesale customers in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne counties. The regional water system consists of water conveyance, treatment, and distribution facilities, and delivers water to retail and wholesale customers. The existing regional system includes over 280 miles of pipelines, over 60 miles of tunnels, 11 reservoirs, five pump stations, and two water treatment plants. The SFPUC currently delivers an annual average of about 265 mgd of water to its customers. The source of the water supply is a combination of local supplies from streamflow and runoff in the Alameda Creek watershed and in the San Mateo and Pilarcitos Creeks watersheds (referred to together as the Peninsula watersheds), augmented with imported supplies from the Tuolumne River watershed. Local watersheds provide about 15 percent of total supplies and the Tuolumne River provides the remaining 85 percent.

Beginning on **Page 1-5** of the Draft EIR, "1.6.1 SFPUC Water System Improvement Program" has been changed as follows:

1.6.1 SFPUC Water System Improvement Program

On October 30, 2008, t~~T~~he SFPUC ~~is proposing to~~ adopted ~~and implement~~ a regional WSIP (known as the "Phased WSIP Variant") (refer to www.sfwater.org; SFPUC, 2008~~6; see also SFPU Resolution 08-0200~~). The WSIP would improve the regional system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area through the year 2018~~2030~~ and would establish level of service goals and system performance objectives. The proposed program area spans seven counties—Tuolumne, Stanislaus, San Joaquin, Alameda, Santa Clara, San Mateo, and San Francisco.

The WSIP includes ~~would implement~~ a ~~proposed~~ water supply strategy and modifications to ~~option, modify~~ system operations, and construction of a series of facility improvement projects. The proposed project, along with several other facility improvement projects, is a component of the WSIP.[1] The overall goals of the WSIP are to maintain high-quality water; reduce vulnerability to earthquakes; increase delivery reliability and improve the ability to maintain the system; meet customer water supply needs ~~purchase requests in nondrought and drought periods~~; enhance sustainability in all system activities; and achieve a

[1] The proposed project is listed as three separate projects in the WSIP ~~Draft~~ PEIR: the Tesla Portal Disinfection Facility, the Hetch Hetchy Advanced Disinfection, and the Lawrence Livermore Supply Improvements. For purposes of this EIR, these three projects are evaluated as one project given their geographic proximity, construction schedule, and the interrelated function of the two proposed facilities at the Tesla Portal site.

cost-effective, fully operational system (refer to Table 2-1, WSIP Goals and Objectives). To further these program goals, the WSIP also includes objectives that address system performance in the areas of water quality, seismic reliability, delivery reliability, and water supply through the year 2018~~2030~~. (See SFPUC Resolution No. 08-0200.)~~The regional water system consists of water conveyance, treatment, and distribution facilities, and delivers water to retail and wholesale customers.~~

To address the potential environmental impacts of the WSIP, the San Francisco Planning Department prepared a Program EIR (PEIR), which was certified by the San Francisco Planning Commission on October 30, 2008 (San Francisco Planning Commission Motion No. 17734). At a project-level of detail, the PEIR evaluated the environmental impacts of the WSIP's water supply strategy and, at a program level of detail, it evaluated the environmental impacts of the WSIP's facility improvement projects. The following sections summarize the WSIP and system operation strategy, along with WSIP's impacts and mitigation measures, as identified in the PEIR.

~~The following sections summarize the analysis contained in the Draft PEIR regarding the WSIP water supply option and system operation strategy, as well as the impacts and mitigation measures, as identified in the Draft PEIR. The San Francisco Planning Department is currently preparing responses to the comments received from public agencies and the general public on the Draft PEIR.~~

Program Description ~~WSIP Water Supply Option~~

The WSIP involves phased implementation of a water supply strategy to meet projected water demand through 2018. It also includes full implementation of all proposed WSIP facility improvement projects to insure that the public health, seismic safety and delivery reliability goals are achieved as soon as possible.[2] Under the WSIP, the SFPUC established an interim mid-term planning horizon – 2018. Thus, the SFPUC made a decision about providing water supply to its customers through 2018 only, and is deferring a decision regarding long-term water supply after 2018 and through 2030 until it undertakes further water supply planning and demand analysis.

The WSIP includes the following key program elements:

- Full implementation of all of the 17 proposed WSIP facility improvement projects described in the PEIR.

[2] The size and design of the WSIP facility improvement projects are driven by the SFPUC's system performance objectives and would not change as a result of the water supply decision included as part of the WSIP. (SFPUC Resolution No. 08-0200.)

- Water supply delivery to regional water system customers through 2018 only of 265 mgd average annual target delivery originating from the Tuolumne, Alameda and Peninsula watersheds. This includes 184 mgd for the wholesale customers (including 9 mgd for the cities of San Jose and Santa Clara), and 81 mgd for the retail customers.

- Development of 20 mgd of conservation, recycled water and groundwater within the SFPUC service area (10 mgd in the retail service area and 10 mgd wholesale service area).

- Dry year transfer from Modesto and/or Turlock Irrigation Districts of about 2 mgd coupled with the Westside Groundwater Basin conjunctive-use project to meet the drought year goal of limiting rationing to no more than 20 percent on a systemwide basis.

- Re-evaluation of 2030 demand projections, potential regional water system purchase requests, and water supply options by 2018 and a separate SFPUC decision in 2018 regarding regional water system water deliveries after 2018.

- Financial incentives to limit water sales to an annual average of 265 mgd from the watersheds.

The WSIP would not provide water supply to meet 300 mgd average annual customer purchase requests in 2030 as proposed under the original WSIP. Rather, under the WSIP, the SFPUC will deliver to customers up to 265 mgd from the SFPUC watersheds on an average annual basis. While average annual deliveries from the SFPUC watersheds would be limited to 265 mgd, such that there would be no increase in diversions from the Tuolumne River to serve additional demand, there would be a small increase in average annual Tuolumne River diversions of about 2 mgd over existing conditions in order to meet delivery and drought reliability goals through 2018.

The SFPUC must maintain water deliveries to all its customers for the protection of public health and safety. Therefore, the SFPUC will work with its customers to develop financial incentives to limit water sales to an average annual amount of 265 mgd from the watersheds through 2018. With the projected 20 mgd of conservation, recycled water, and groundwater projects, the system would meet average daily demand of 285 mgd in 2018. ~~Through the WSIP, the SFPUC proposes a water supply option to address the water supply level of service objective of meeting a projected 35 mgd increase in customer purchase requests by 2030, and to provide drought-year delivery with a maximum systemwide rationing of 20 percent. This strategy includes maximizing the use of local watershed supplies, increasing diversions from the Tuolumne River under existing water rights, and development of new local resources, including additional conservation, water recycling, and groundwater supply programs in~~

~~San Francisco. This combination of water supply sources is expected to fully meet customer purchase requests during non-drought years through 2030.~~

~~During periods of prolonged drought, the WSIP proposes supplemental sources to augment the non-drought sources described above. The SFPUC proposes to secure a water transfer with the Turlock Irrigation District and/or Modesto Irrigation District to provide supplemental dry-year water from the Tuolumne River. Further, the SFPUC proposes to implement a groundwater banking program in the Westside Groundwater Basin in San Mateo County. In addition, two of the WSIP facility improvement projects involve restoring the historic operating capacities of the Calaveras and Lower Crystal Springs reservoirs, which would augment drought supplies for the regional system. Also, during drought years under the WSIP the SFPUC would include up to 20 percent systemwide rationing.~~

Beginning on **Page 1-7** of the Draft EIR, text beginning with the title "Summary of Water Supply/Operations Impacts and Mitigation Measures" has been changed as follows:

Summary of Water Supply/Operations Impacts ~~and Mitigation Measures~~

The ~~WSIP Draft~~ PEIR analyze~~s~~d potential water supply and system operations impacts within the following geographic regions: the Tuolumne River, Alameda Creek, Peninsula, and Westside Basin groundwater resources systems. The ~~WSIP Draft~~ PEIR also identifie~~s~~d the cumulative effects of implementing the WSIP ~~water supply option~~ and system operations in combination with other past, present, and reasonably foreseeable future projects within each of these watersheds. It also discusse~~s~~d the potential effects of climate change and global warming on the regional water system.

~~Because of the proposed increased Tuolumne River diversions and operational changes, t~~The WSIP would result in changes in reservoir levels and associated changes in downstream flows in rivers and~~or~~ creeks in the three affected watersheds, potentially resulting in ~~geomorphology,~~ groundwater, water quality, fisheries, and terrestrial biological resource~~s recreational, and visual~~ impacts. In the event that deliveries to customers exceed 265 mgd, ~~Tuolumne River watershed,~~ streamflow changes in the Tuolumne River watershed could affect fisheries and terrestrial biological resources~~downstream water supplies and hydropower generation~~. In the Alameda Creek and Peninsula watersheds, the ~~proposed~~ WSIP, which includes ~~would include~~ restoring the historical storage capacities of Calaveras and Lower Crystal Springs Reservoirs, could affect~~potentially affecting~~ reservoir levels, downstream flows, fisheries, and terrestrial biological resources~~, and visual resources~~. In addition, similar to the originally proposed WSIP, the WSIP will ~~would~~ develop groundwater supplies in

the North Westside Groundwater Basin as well as a conjunctive-use program in the South Westside Groundwater Basin.

~~The WSIP Draft PEIR identifies potential beneficial effects on energy resources (increased hydroelectric resource) and on fisheries in Calaveras Reservoir, Calaveras Creek, Alameda Creek below the convergence with Calaveras Creek, and San Antonio Reservoir.~~

The following list summarizes the WSIP ~~water supply~~ impacts identified in the ~~Draft~~ PEIR that are potentially significant but mitigable; potentially significant and unavoidable; and significant and unavoidable. As set forth in the PEIR, the San Francisco Planning Department ~~The WSIP Draft PEIR has~~ determined the potential environmental impacts on all resources not listed below would be less than significant and no mitigation measures would be required. (Refer to Chapter 6 and Appendix B.1 for further discussion of the WSIP water supply impact analysis).

Page 1-8 of the Draft EIR, the section under "Potentially Significant But Mitigable WSIP Water Supply Impacts" has been changed as follows:

Potentially Significant But Mitigable WSIP Water Supply Impacts

- Fisheries Resources: Tuolumne River (below La Grange Dam, only when average annual deliveries from the watersheds exceed 265 mgd); Alameda Creek~~; Pilarcitos Reservoir and Creek~~

- Terrestrial Biological Resources: Tuolumne River (below La Grange Dam – only when average annual deliveries exceed 265 mgd; and impacts on alluvial features that support meadow and riparian habitat from O'Shaughnessy Dam to Don Pedro Reservoir); Calaveras Reservoir; Alameda Creek; Calaveras Creek; Upper and Lower Crystal Springs Reservoir~~; Pilarcitos Reservoir; Pilarcitos Creek~~

- ~~Recreational and Visual Resources: Alameda Creek system~~

- ~~Streamflow: Pilarcitos Reservoir; Pilarcitos Creek~~

- Groundwater: Pumping overdraft; change in water levels in Lake Merced and other surface water features; seawater intrusion due to decreased groundwater levels; contamination of drinking water

Page 1-8 of the Draft EIR, the section under "Potentially Significant and Unavoidable WSIP Water Supply Impacts" the following text has been revised per an editorial error:

Potentially Significant and Unavoidable WSIP Water Supply Impacts

- Fisheries: Upper and Lower Crystal Springs Reservoir
- Growth Inducement: SFPUC Service Area

Page 1-8 of the Draft EIR, the first paragraph under "Alternatives to the WSIP" has been changed as follows:

Alternatives to the WSIP

The ~~Draft~~ PEIR evaluated~~s~~ seven alternatives to the ~~proposed~~ WSIP, listed below, because of their apparent ability to meet most of the WSIP's goals, their ability to reduce one or more of the potentially significant impacts associated with program implementation, their potential feasibility, and their collective ability to provide a reasonable range of alternatives to foster informed decision-making and public participation. Analysis of the No Program Alternative is included as required by CEQA. Section 9.2 in the Alternatives chapter, and Appendix B.3 presents a more detailed summary of these alternatives.

Page 1-9 of the Draft EIR, following the last bulleted item the following sentence has been added and the subsequent paragraph modified as follows:

The adopted WSIP (see SFPUC Resolution No. 08-0200) incorporates elements of three alternatives: the No Purchase Request Alternative, the Aggressive Conservation/Water Recycling and Groundwater Alternative, and the Modified WSIP Alternative.

CEQA also requires the identification of an environmentally superior alternative from among the proposed project and the set of alternatives evaluated. The ~~WSIP~~ Draft PEIR identified the Modified WSIP Alternative as the environmentally superior alternative~~.~~ for the 2030 planning horizon because it would reduce key impacts of the originally proposed WSIP on natural resources along the lower Tuolumne River, in Alameda and Pilarcitos Creeks, and in/around Crystal Springs and Pilarcitos Reservoirs, but it would continue to meet the WSIP's primary goals and objectives. Like the adopted WSIP (known as the "Phased WSIP Variant" in the Final PEIR), the Modified WSIP Alternative would maximize the use of existing facilities and the largely gravity-driven system without also requiring the construction of additional major facilities called for under many other alternatives, or substantially increasing the energy demand of the system or need for pumping. The Modified WSIP Alternative would have more impacts on the upper Tuolumne River, and possibly less on the Lower Tuolumne River. The adopted WSIP is substantially similar to the Modified WSIP Alternative in that it includes essentially the same elements through 2018.

Beginning on **Page 1-10,** portions of Table 1-1 of the Draft EIR have been changed as follows:

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
Biological Resources			
Impact 4.6-1: Impacts on wetlands and aquatic resources (construction-related impacts) and Impact 4.6-4: Impacts on wetlands and aquatic resources (operational impacts)	Tesla Portal: PSM Thomas Shaft: N/A	Mitigation Measure 4.6-1a – Participate in the SJMSCP: Prior to the commencement of construction activities, SFPUC shall coordinate with the Joint Powers Authority (JPA)/Technical Advisory Committee (TAC), implement relevant ITMMs for applicable species (as identified in Mitigation Measures 4.6-3b through 4.6-3l, below) and pay any necessary fees to fund offsite compensation under the terms of the SJMSCP to provide replacement values that are equal to that of the permanent loss of ~~0.308~~ 3.2 acres of California annual grasslands and 0.01 acre of ruderal/disturbed land, and temporary impacts to 11.72 acres of California annual grassland and 0.96 acre of ruderal/disturbed land ~~habitat values of the artificial wetland, the temporary loss of <0.001 acre of ephemeral drainage, the temporary loss and permanent conversion of natural lands~~, and incidental take authorization for special-status species.	Tesla Portal and Thomas Shaft
Impact 4.6-2: Impacts to sensitive habitats, common habitats, and heritage trees	Tesla Portal: PSM Thomas Shaft: LS	Mitigation Measure 4.6-2 – Return Site to Pre-Construction Condition: Vegetation removal and soil disturbance shall be limited to the minimum amount necessary for project implementation, especially where the existing access road comes near the artificial wetland, and where the proposed pipeline would cross both the artificial wetland and the ephemeral drainage. Where soils are disturbed and/or vegetation removed on the project site, such as in the construction staging area, the site shall be returned to pre-project conditions (i.e., return site contours to pre-project profiles, restore original grades where possible, lightly compact loose soils or aerate compacted soils) where necessary. Where grading occurs, 12 inches of topsoil shall be salvaged and respread in graded areas as appropriate. When natural vegetation is disturbed, small areas (e.g., less than 100 square feet in size) shall be allowed to re-vegetate passively, while larger disturbed areas (e.g., more than 100 square feet in size or in areas prone to erosion such as sloped areas) shall be re-seeded with locally available native grasses and forbs (as needed).	Tesla Portal ~~and Thomas Shaft~~
		Mitigation Measure 4.6-3c – Implement Incidental Take Minimization Measures for San Joaquin Kit Fox: SFPUC shall implement the ITMMs identified for the San Joaquin kit fox under the SJMSCP to reduce the level of impact on the San Joaquin kit fox. Mitigation measures defined by the SJMSCP and the USFWS to protect the San Joaquin kit fox include the following: • A qualified biologist with demonstrated experience in kit fox biology, identification, and survey techniques shall conduct preconstruction surveys two calendar weeks to 30 calendar days prior to commencement of ground disturbance. Surveys shall be conducted by qualified biologists. When surveys identify potential dens (potential dens are defined as burrows at least four inches in diameter which open up within two feet), potential den entrances shall be dusted for three	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		calendar days to register track of any San Joaquin kit fox present. If no San Joaquin kit fox activity is identified, potential dens may be destroyed. • If San Joaquin kit fox activity is identified, then dens shall be monitored to determine if occupation is by an adult fox only or is a natal den (natal dens usually have multiple openings). If the den is occupied by an adult only, the den may be destroyed when the adult fox has moved or is temporarily absent. If the den is a natal den, a buffer zone of 250 feet shall be maintained around the den until the biologist determines that the den has been vacated. • Where San Joaquin kit fox are identified, the provisions of the U.S. Fish and Wildlife Service's published "Standardized Recommendations for Protection of the San Joaquin kit fox Prior to or During Ground Disturbance" shall apply (except that preconstruction survey protocols shall remain as established in this paragraph). These standards include provisions for educating construction workers regarding the kit fox, keeping heavy equipment operating at safe speeds, checking construction pipes for kit fox occupation during construction and similar low or no-cost activities.	
		Mitigation Measure 4-6.3e – Breeding Season Surveys: ~~Conduct Pre-Construction Surveys for Burrowing Owls: In January, and again no more than two weeks before construction, a survey for burrows and burrowing owls shall be conducted by a qualified biologist within 500 feet of the project (access permitting). The survey will conform to the protocol described by the California Burrowing Owl Consortium in the Burrowing Owl Survey Protocol and Mitigation Guidelines (California Burrowing Owl Consortium, 1993), which includes up to four surveys on different dates if there are suitable burrows present.~~ ~~If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with the California Department of Fish and Game (CDFG), as to whether or not work will affect the occupied burrows or disrupt reproductive behavior.~~ ~~If it is determined that construction will not affect occupied burrows or disrupt breeding behavior, construction will proceed without any restriction or mitigation measures.~~ ~~If it is determined that construction will affect occupied burrows during August through February, the subject owls will be passively relocated from the occupied burrow(s) using one-way doors. There will be at least two unoccupied burrows suitable for burrowing owls within 300 feet of the occupied burrow before one-way doors are installed. Artificial burrows will be in place at least one-week before one-way doors are installed on occupied burrows. One-way doors will be in place for a minimum of 48 hours before burrows are excavated.~~ Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below:	Tesla Portal~~ and Thomas Shaft~~

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		• If project schedule permits, a qualified biologist will survey for burrows and burrowing owls during the breeding season (February 1 to August 31), immediately preceding construction. Surveys will be conducted within 500 feet of the project boundary (access permitting) in accordance with the California Burrowing Owl Consortium (1993) guidelines or as otherwise determined by CDFG. Burrows would be inspected for signs of owl activity (tracks, pellets, feathers, etc.). The locations of burrowing owl sightings, occupied burrows, and burrows with signs of owl activity will be marked on a map of the project area at a scale sufficient to accurately show the distance of active burrows to the limits of construction. Surveys will be conducted on at least four separate dates during the breeding season in areas where suitable burrows are present. If possible, surveys will be conducted during the peak of the burrowing owl breeding season, generally between April 15 and July 15. • If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with CDFG, as to whether work will affect the occupied burrows or disrupt reproductive behavior. • If it is determined that construction will not affect occupied burrows or disrupt breeding behavior, construction will proceed without any restrictions or mitigation measures.	
		Mitigation Measure 4-6.3f – Winter Surveys: ~~– Relocate Burrowing Owls: During the non-breeding season (September 1 through January 31) burrowing owls occupying the project site should be evicted from the project site by passive relocation as described in the CDFG's Staff Report on Burrowing Owls.~~ Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below: • If birds are not observed during breeding season surveys, or if breeding season surveys are infeasible due to project scheduling, or if construction will occur during the wintering season, a winter survey will be conducted to identify non-breeding residents of the project site. Winter surveys will be conducted within 500 feet of the project site (access permitting) or as otherwise determined by CDFG during the period when wintering owls are most likely to be present (December 1 to January 31). The locations of burrowing owl sightings, occupied burrows, and burrows with signs of owl activity will be marked on a map of the project area at a scale sufficient to accurately show the distance of active burrows to the limits of construction. • If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with CDFG, as to whether or not work will affect the occupied burrows.	Tesla Portal ~~and Thomas Shaft~~

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		• If it is determined that construction will not affect occupied burrows, construction will proceed without any restrictions or mitigation measures. • If it is determined that construction will affect occupied burrows, the subject owls will be passively relocated from the occupied burrow(s) using one-way doors prior to the onset of breeding season. Owls will be encouraged to relocate to alternate burrows that are at least 160 feet from the construction limits. One alternate natural or artificial burrow for each burrow excavated will be in place at least one week before one-way doors are installed on occupied burrows. One-way doors will be in place for a minimum of 48 hours before burrows are excavated.	
		Mitigation Measure 4-6.3g – Fall Surveys: ~~– Buffer Zone around Burrows Occupied by Burrowing Owls: During the breeding season (February 1 through August 31) occupied burrows shall not be disturbed and shall be provided with a 100-foot protective buffer until and unless the TAC, with the concurrence of the Permitting Agencies' representatives on the TAC; or unless a qualified biologist approved by the Permitting Agencies verifies through noninvasive means that either: 1) the birds have not begun egg laying, or 2) juveniles from the occupied burrows are foraging independently and are capable of independent survival. Once the fledglings are capable of independent survival, the burrow can be destroyed.~~ Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below: • If surveys must be conducted between September 1 and November 30 (which is outside of the time windows specified above), a qualified biologist will conduct a survey for burrows and burrowing owls no more than thirty (30) days prior to ground-disturbing activity. If necessary, resident owls will be passively relocated from occupied burrows, as described above. If construction activities are still ongoing beyond November 30, then winter surveys will be conducted during December and January.	Tesla Portal
		Mitigation Measure 4.6-3h – Conduct Pre-Construction Surveys for Swainson's Hawk: A qualified biologist shall conduct a preconstruction survey for Swainson's hawk, prior to the commencement of any ground disturbing construction activities (e.g., grass/vegetation/brush/tree removal, soil excavation, grading, vehicle access, staging of materials or vehicles, large scale materials off-haul or delivery, construction of temporary or permanent access roads). In the case that Swainson's hawks are found nesting in the area, the SFPUC will notify CDFG. At a minimum~~In addition,~~ the following mitigations regarding Swainson's hawk, as listed from the SJMSCP, will be implemented:	Tesla Portal ~~and Thomas Shaft~~

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		• If a nest tree becomes occupied during construction activities, then all construction activities shall remain a distance of two times the dripline of the tree, measured from the nest. • If any nest trees need to be removed, they may be removed between September 1 and February 15, when the nests are unoccupied. The following two measures will also be implemented: • If any unoccupied nests are found during preconstruction surveys, these nests may be removed when the nests are unoccupied. • If any occupied nests are found during preconstruction surveys, then all construction activities shall remain at a distance of ¼ mile (1,320 feet), unless CDFG agrees to other equally effective measures ~~are agreed to by CDFG~~ (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc).	
		Mitigation Measure 4.6-3i – Implement Incidental Take Minimization Measures for White-Tailed Kite: SFPUC shall implement the ITMM identified for the white-tailed kite under the SJMSCP, which consists of the following: • A qualified biologist shall conduct preconstruction surveys and investigate all potential nesting trees on the project site (e.g., especially tree tops 15-59 feet above the ground in oak, willow, eucalyptus, cottonwood, or other deciduous trees), during the nesting season (February 15 to September 15) whenever white-tailed kites are noted on site or within the vicinity of the project site during the nesting season. • If the species is found nesting, a setback of 100 feet from nesting areas shall be established and maintained during the nesting season for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective measures ~~are agreed to by CDFG~~ (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc.) and CDFG shall be notified of the proposed buffer zone. This setback applies whenever construction or other ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.	Tesla Portal and Thomas Shaft
		Mitigation Measure 4.6-3j – Implement Incidental Take Minimization Measures for California Horned Lark and Northern Harrier: SFPUC shall implement the ITMM identified for the California horned lark and northern harrier under the SJMSCP, which consists of the following:	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		• A qualified biologist shall conduct a preconstruction survey and investigate all potential nesting trees to determine the presence or absence of the species on the project site. • If species are found, a setback of 500 feet from nesting areas shall be established and maintained during the nesting season (February 16 – August 31) for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective measures ~~are agreed to by CDFG~~ (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc.), or offsite compensation shall be provided, and CDFG shall be notified of the proposed buffer zone. If a setback is used, this setback would apply whenever construction or other ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.	
		Mitigation Measure 4.6-3k – Conduct Pre-Construction Surveys for Golden Eagle: Prior to the start of construction, a qualified biologist shall conduct golden eagle surveys as required by the SJMSCP. Additionally, SFPUC shall implement the ITMM identified for the golden eagle under the SJMSCP, which consists of the following: • When a site inspection indicates the presence of a nesting golden eagle, CDFG will be notified and a setback of 500 feet from the nesting area shall be established and maintained during the nesting season (normally approximately February 1 – June 30) for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective measures ~~are agreed to by CDFG~~ (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc.). This setback applies whenever construction or other ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.	Tesla Portal and Thomas Shaft
		Mitigation Measure 4.6-3l – Conduct Pre-Construction Surveys for Ferruginous Hawk and Prairie Falcon: Prior to the start of construction, a qualified biologist shall conduct surveys for ferruginous hawk and prairie falcon as required by the SJMSCP. These species currently do not nest in San Joaquin County and are not expected to nest in the County over the life of the SJMSCP. Therefore, in the highly unlikely event that one of these species is found nesting on a project site, SFPUC shall notify CDFG of the proposed buffer zone and a setback of 500 feet from the nesting area shall be established and maintained for the period encompassing nest building and continuing until fledglings leave the nests, unless CDFG agrees to other equally effective measures. ITMMs shall be formulated prior to ground	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		disturbance by the TAC and approved by the JPA with the concurrence of the Permitting Agencies' representatives on the TAC in accordance with the SJMSCP's Adaptive Management Plan. ITMMs may consist of preconstruction surveys, avoidance techniques, and buffer areas.	
Cultural Resources			
Impact 4.7-1: Potential to disturb or destroy paleontological resources.	Tesla Portal: PSM Thomas Shaft: PSM	Mitigation Measure 4.7-1a – Paleontological Monitoring During Excavation ~~Work~~: The SFPUC shall retain a qualified professional paleontologist to monitor excavations starting at the depth of 10 feet deep during construction at the Tesla Portal site for paleontological resources. Monitoring shall continue at the Tesla Portal site until the supervising qualified paleontologist determines that no native sediments are present or that significant paleontological resources are not likely to be discovered.	Tesla Portal
Impact 4.7-2: Potential to disturb or destroy unknown prehistoric archaeological resources or human remains.	Tesla Portal: PSM Thomas Shaft: PSM	Mitigation Measure 4.7-2a – Accidental Archaeological Discovery: SFPUC Standard Construction Measure #9 for cultural resources requires that construction activities be suspended immediately if there is any indication of an archaeological resource. To avoid any potential adverse effect from the proposed project on accidentally discovered buried or submerged historical resources as defined in CEQA Guidelines Section 15064.5(a)(c), the SFPUC shall distribute the Planning Department archaeological resource "ALERT" sheet to the project prime contractor; to any project subcontractor (including firms specializing in demolition, excavation, grading, foundation, pile driving, etc.); or utilities firm involved in soil disturbing activities within the project site. Prior to any soil disturbing activities being undertaken, each contractor is responsible for ensuring that the "ALERT" sheet is circulated to all field personnel including, machine operators, field crew, pile drivers, supervisory personnel, etc. The SFPUC shall provide the Environmental Review Officer (ERO) with a signed affidavit from the responsible parties (prime contractor, subcontractor(s), and utilities firm) ~~to the ERO~~ confirming that all field personnel have received copies of the "ALERT" sheet. Should any indication of an archaeological resource be encountered during any soils disturbing activity of the project, the contractor and/or the SFPUC will immediately notify the ERO and will immediately suspend any soils disturbing activities within 100 feet of the discovery until the ERO has determined what additional measures should be undertaken. If the ERO determines that an archeological resource may be present within the project site, the SFPUC shall retain the services of a qualified archeological consultant. The archeological consultant shall advise the ERO as to whether the discovery is an archeological resource that ~~,~~ retains sufficient integrity, and is of potential scientific/historical/cultural significance. If an archeological resource is present, the archeological consultant shall identify and evaluate the archeological resource. The	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		archeological consultant shall make a recommendation as to what action, if any, is warranted. Based on this information, the ERO may require, if warranted, specific additional measures to be implemented by the SFPUC. Measures might include: preservation in situ of the archeological resource; an archaeological monitoring program; or an archeological ~~testing~~ evaluation program. If an archeological monitoring program or archeological ~~testing~~ evaluation program is required, it shall be consistent with the MEA WSIP Archaeological Guidance (San Francisco Planning Department 2008) ~~guidelines~~ for such programs. The ERO may also require that the SFPUC immediately implement a site security program if the archeological resource is at risk from vandalism, looting, or other damaging actions. The project archeological consultant shall submit an accidental discovery Archaeological Data Recovery Report (ADRR) to the ERO, which, in addition to the usual contents of the ADRR, includes an evaluation of ~~the appropriate report(s) in accordance with the MEA WSIP Projects Archaeological Guidance series that evaluates~~ the historical significance of any discovered archeological resource, as well as describing ~~and describes~~ the archeological and historical research methods employed in the archeological monitoring/data recovery program(s) undertaken, and presenting, analyzing, and interpreting the recovered data.. Information that may put at risk any archeological resource shall be provided in a separate removable insert within the final report. Once approved by the ERO, copies of the ADRR ~~report(s)~~ shall be distributed as follows: the relevant California Historical Resources Information System Information Center shall receive one (1) copy and the ERO shall receive a copy of the transmittal letter of the ADRR ~~report~~ to the Information Center. The MEA shall receive three copies of the ADRR ~~each report~~ along with copies of any formal site recordation forms (CA DPR 523 series) and/or documentation for nomination to the National Register of Historic Places/California Register of Historical Resources. The SFPUC shall receive copies of the ADRR~~report(s) as requested~~ in the number requested. In instances of high public interest in or the high interpretive value of the resource, the ERO may require a different final report content, format, and distribution than that presented above.	
		Mitigation Measure 4.7-2b – Treatment of Human Remains: The treatment of human remains and of associated or unassociated funerary objects discovered during any soils disturbing activity shall comply with applicable State laws. This shall include immediate notification of the San Joaquin County Coroner and in the event of the coroner's determination that the human remains are Native American ~~remains~~, notification of the California State Native American Heritage Commission (NAHC) who shall appoint a Most Likely Descendant (MLD) (Public Resources Code Section 5097.98). The	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		archaeological consultant, SFPUC, and MLD shall make all reasonable efforts to develop an agreement for the treatment of, with appropriate dignity, human remains and associated or unassociated funerary objects (CEQA Guidelines Section 15064.5(~~e~~d)). The agreement should take into consideration the appropriate excavation, removal, recordation, analysis, custodianship, curation, and final disposition of the human remains and associated or unassociated funerary objects. California Public Resources Code ~~State law~~ allows 24 hours to reach agreement on these matters. If the MLD~~s~~ and the other parties do not agree on the reburial method, the project will follow Section 5097.98(b) of the California Public ~~r~~Resources ~~c~~Code which states, "the landowner or his or her authorized representative shall reinter the human remains and items associated with Native American burials with appropriate dignity on the property in a location not subject to further subsurface disturbance."	
Air Quality			
Impact 4.9-1: Construction emissions of criteria pollutants	Tesla Portal: PSM Thomas Shaft: PSM	Mitigation Measure 4.9-1b – SJVAPCD Exhaust Control Measures: The following mitigation measures will be implemented during construction of the proposed project to reduce exhaust emissions: *(1) SJVAPCD Guide to Assessing and Mitigating Air Quality Impacts Mitigation Measures:* To limit exhaust emissions within the San Joaquin Region, the SJVAPCD specifies the following exhaust controls for heavy-duty equipment (scrapers, graders, trenchers, earthmovers, etc.). The SFPUC will include these measures, where feasible and applicable, in contract specifications: • Idling time (e.g., ~~10~~5-minute maximum) shall be minimized. • The hours of operation of heavy-duty equipment and/or the amount of equipment in use shall be limited. • Activity management (e.g., rescheduling activities to reduce short-term impacts) shall be implemented. *(2) Regulation IX – Mobile and Indirect Sources, Rule 9510 Mitigation Measures:* Rule 9510 applies to any project subject to discretionary approval by a public agency that ultimately results in the construction of a new building, facility, or structure or reconstruction of a building, facility, or structure for the purpose of increasing capacity or activity and also involving 9,000 square feet of space. Rule 9510 requires exhaust emissions for construction equipment greater than 50 horsepower used or associated with a development project to be reduced by the following amounts from the statewide average as estimated by the California Air Resources Board (CARB): • 20% of the total NOX emissions	Tesla Portal and Thomas Shaft

TABLE 1-1
SUMMARY OF POTENTIALLY SIGNIFICANT IMPACTS AND MITIGATION MEASURES

Environmental Impact	Impact Designation	Mitigation Measures	Applicable Site
		• 45% of the total PM10 exhaust emissions An applicant may reduce construction emissions on-site by using less polluting construction equipment, which can be achieved by utilizing add-on controls, cleaner fuels, or newer lower emitting equipment. The requirements listed above can also be met through the payment of an off-site emissions reduction fee. The following mitigation measures will be selectively applied to achieve compliance with the emission reductions set forth by Rule 9510: • Selected construction equipment with engines equal to or greater than 50 horsepower will: – Be equipped with Tier 2 diesel engines as defined in Title 13, CCR, §2423 – Must be equipped with verified Level 3 (at least 85% reduction of PM from the baseline emission level) Diesel Emission Control Strategies as defined in Title 13, CCR, §2700 through 2710 • All construction vehicles will undergo monthly maintenance. Preventive maintenance includes complying with the manufacturer's service recommendations, using recommended types of fuel, maintaining proper fluid levels (such as oil, coolant, brake, and transmission), ensuring proper tire pressure, working signals, lights (including headlamps, turn-signal lights, tail lights, and brake lights), and brakes.	

Page 1-27, the references section for the Executive Summary of the Draft EIR has been modified as follows:

~~San Francisco Public Utilities Commission (SFPUC), *Water System Improvement Program*, January 2006d.~~

San Francisco Public Utilities Commission (SFPUC), Water System Improvement Program California Environmental Quality Act Findings: Findings of Fact, Evaluation of Mitigation Measures and Alternatives, and Statement of Overriding Considerations, SFPUC Resolution No. 08-0200, October 30, 2008.

Chapter 2 Introduction

Page 2-1 of the Draft EIR**,** the paragraph under "2.1.1 SFPUC Regional Water System Overview" has been revised as follows:

2.1.1 SFPUC Regional Water System Overview

The City and County of San Francisco (CCSF), through the SFPUC, owns and operates a regional water system that extends from the Sierra Nevada to San Francisco and serves 2.4 million people in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne counties. The regional water system consists of water conveyance, treatment, and distribution facilities, and delivers water to retail and wholesale customers. The existing regional system includes over 280 miles of pipelines, over 60 miles of tunnels, 11 reservoirs, five pump stations, and two water treatment plants. The SFPUC currently delivers an annual average of about 265 million gallons per day (mgd) of water to its customers. The source of the water supply is a combination of local supplies from streamflow and runoff in the Alameda Creek watershed and in the San Mateo and Pilarcitos Creeks watersheds (referred to together as the Peninsula watersheds), augmented with imported supplies from the Tuolumne River watershed. Local watersheds provide about 15 percent of total supplies and the Tuolumne River provides the remaining 85 percent. Figure 2-1 (SFPUC Regional Water System) illustrates the general location of the SFPUC regional system and water supply watersheds.

Page 2-3 of the Draft EIR**,** the paragraph under "2.1.2 SFPUC Water System Improvement Program" has been revised as follows:

2.1.2 SFPUC Water System Improvement Program

On October 30, 2008, t~~T~~he SFPUC ~~is proposing to~~ adopted ~~and implement~~ a regional Water System Improvement Program (known as the "Phased WSIP Variant") (refer to www.sfwater.org; SFPUC, 2008~~6~~; also see SFPUC Resolution No. 08-0200). The adopted WSIP would improve the regional system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area through the year 2018~~2030~~ and

would establish level of service goals and system performance objectives. The proposed program area spans seven counties—Tuolumne, Stanislaus, San Joaquin, Alameda, Santa Clara, San Mateo, and San Francisco.

The WSIP includes ~~would implement~~ a ~~proposed~~ water supply strategy, ~~option, modify~~ modifications to system operations, and construction of ~~construct~~ a series of facility improvement projects. The proposed project, along with several other facility improvement projects, is a component of the WSIP.[1] The overall goals of the WSIP are to maintain high-quality water; reduce vulnerability to earthquakes; increase delivery reliability and improve the ability to maintain the system; meet customer purchase requests in nondrought and drought periods; enhance sustainability in all system activities; and achieve a cost-effective, fully operational system (refer to Table 2-1). To further these program goals, the WSIP also includes objectives that address system performance in the areas of water quality, seismic reliability, delivery reliability, and water supply through the year 2018.~~2030. The regional water system consists of water conveyance, treatment, and distribution facilities, and delivers water to retail and wholesale customers.~~

Beginning on **Page 2-3** of the Draft EIR**,** Table 2-1 has been revised as follows:

TABLE 2-1
WSIP GOALS AND OBJECTIVES

Program Goal	System Performance Objective
Water Quality – *maintain high quality water*	▪ Design improvements to meet current and foreseeable future federal and state water quality requirements. ▪ Provide clean, unfiltered water originating from Hetch Hetchy Reservoir and filtered water from local watersheds. ~~filter all other surface water sources.~~ ▪ Continue to implement watershed protection measures.
Seismic Reliability – *reduce vulnerability to earthquakes*	▪ Design improvements to meet current seismic standards. ▪ Deliver basic service to the three regions in the service area (East/South Bay, Peninsula, and San Francisco) within 24 hours after a major earthquake. Basic service is defined as average winter-month usage, and the performance objective for the regional system is 229 million gallon per day (mgd). The performance objective is to provide delivery to at least 70 percent of the turnouts (i.e., water diversion connecting points from the regional system to customers) in each region, with 104, 44 and 81 mgd delivered to East/South Bay, Peninsula, and San Francisco regions, respectively. ▪ Restore facilities to meet average-day demand of up to 300 mgd within 30 days after a major earthquake.

[1] The proposed project is listed as three separate projects in the WSIP ~~Draft~~ PEIR: the Tesla Portal Disinfection Facility, the Hetch Hetchy Advanced Disinfection, and the Lawrence Livermore Supply Improvements. For purposes of this EIR, these three projects are evaluated as one project given their geographic proximity, construction schedule, and the interrelated function of the two proposed facilities at the Tesla Portal site.

TABLE 2-1
WSIP GOALS AND OBJECTIVES

Delivery Reliability – *increase delivery reliability and improve the ability to maintain the system*	▪ Provide operational flexibility to allowed planned maintenance shutdown of individual facilities without interrupting customer service. ▪ Provide operational flexibility to minimize the risk of service interruption due to unplanned facility upsets or outages. ▪ Provide operational flexibility and system capacity to replenish local reservoirs as needed. ▪ Meet estimated average annual demand of up to 300 mgd ~~for 2030~~ under the conditions of one planned shutdown of a major facility for maintenance concurrent with one unplanned facility outage due to a natural disaster, emergency, or facility failure/upset.
Water Supply – *meet customer water needs in nondrought and drought periods*	▪ Meet average annual water demand ~~purchase requests~~ of 265~~300~~ mgd from the SFPUC watersheds for retail and wholesale customers during nondrought years for system demands through 2018~~2030~~. ▪ Meet dry-year delivery needs through 2018~~2030~~ while limiting rationing to a maximum 20 percent systemwide reduction in water service during extended droughts. ▪ Diversify water supply options during nondrought and drought periods. ▪ Improve use of new water sources and drought management, including ~~use of~~ groundwater, recycled water, conservation, and transfers
Sustainability – *enhance sustainability in all system activities*	▪ Manage natural resources and physical systems to protect watershed ecosystems. ▪ Meet, at a minimum, all current and anticipated legal requirements for protection of fish and ~~other~~ wildlife habitat. ▪ Manage natural resources and physical systems to protect public health and safety.
Cost-effectiveness – achieve a cost-effective, fully operational system	▪ Ensure cost-effective use of funds. ▪ Maintain gravity-driven system. ▪ Implement regular inspection and maintenance program for all facilities.

Chapter 3 Project Description

Page 3-1 of the Draft EIR**,** following "3.1.1 Relation to Water System Improvement Program Goals" has been modified as follows:

> The proposed project is part of the San Francisco Public Utilities Commission's (SFPUC's) Water System Improvement Program (WSIP). The WSIP goals and objectives (refer to Table 2-1 in Chapter 2.0, Introduction) were developed based on a planning horizon through 2018 ~~2030~~. The overall goals of the WSIP for the regional water system are to:

Page 3-1 of the Draft EIR**,** following the bulleted list the following paragraph has been added:

> The size and design of the individual WSIP facility improvement projects are driven by the WSIP's system performance objectives and would not change as a result of the WSIP's water supply strategy. The originally proposed WSIP included multiple program goals for improving seismic reliability and water delivery reliability, meeting current and future water quality regulations, and meeting water supply reliability goals. Design and capacity of the WSIP facility improvement projects is driven by all four of the WSIP objectives -- the need to improve system performance for seismic reliability and water delivery reliability as well as maintaining high water quality standards and meeting water supply goals. All four of these objectives are factored into the decision on how to size the WSIP's individual facilities. Even if the goal of meeting projected increases in water supply demands were dropped from the mix of program objectives, the other program goals would cause the SFPUC to design WSIP facility improvement projects of the same size. All the WSIP facilities are sized to reliably deliver an average annual amount of 265 mgd (and up to 300 mgd) in light of the regional system's needs for seismic and delivery reliability during both drought and non-drought periods, and to meet water quality requirements (SFPUC Resolution No. 08-0200).

Page 3-7 of the Draft EIR**,** the paragraph beginning with "Sodium hypochlorite. . ." has been revised per comment C-Larwe-01 as follows:

> *Giardia* inactivation is currently accomplished through the addition of sodium hypochlorite (chlorine) to the regional water supply at the Tesla Disinfection

Facility, which provides adequate contact time for the inactivation of *Giardia*. To provide adequate *Giardia* disinfection to LLNL Site 300, additional ultraviolet (UV) facilities would be installed at Thomas Shaft (see Section 3.2). ~~Sodium hypochlorite~~Chlorine would be fed from the Chemical Process Building and injected into the out flow manifolds. Although the location of the chlorination function at the site would change, the chlorine injection process itself would be essentially unchanged. In addition, to lower the pH of the water, fluoride and CO_2 would be added to improve current water quality management capabilities.

Page 3-11, the heading after the first full paragraph of the Draft EIR has been changed as follows:

3.~~2.3~~3.2 Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)

Page 3-11 of the Draft EIR**,** the last paragraph is revised per comment L-SFLPAB-03 as follows:

Other improvements proposed at the Thomas Shaft site include installation of a 360-square-foot prefabricated structure 10 feet in height within the fenced area atop Thomas Shaft and replacing two existing 100 horse power (hp) pumps with two 30 hp pumps (one active and one standby). A trench, approximately 150 foot by 3 foot by 3 foot would be excavated from the existing Chlorination Facility building to the Thomas Shaft and to the percolation tank (as shown on Figure 3-2). Prior to commencement of this project, fencing will be installed as part of another project (Thomas Shaft Roadway Improvement Project, SFPUC Resolution No. 08-0061) and will remain installed around the steam engine foundation and bucket assembly; this fence will avoid potential inadvertent physical impacts or damage to the resource that could occur during project construction.

Page 3-21 of the Draft EIR, after the last bullet point on the page the following bullet point has been added per comment L-BAWSCA-03:

- Modification to Regional Operational Permit will be issued by the California Department of Public Health for changes in disinfection equipment used (Tesla Portal and Thomas Shaft sites).

Page 3-22, the following reference has been added to the Project Description reference for the Draft EIR:

SFPUC, Thomas Shaft Roadway Improvement Project, SFPUC Resolution No. 08-0061. April 8, 2008.

Chapter 4 Environmental Setting and Impacts

4.1 Approach to Analysis

Beginning on **Page 4.1-4** of the Draft EIR, the section "4.1.2 Water System Improvement Program" has been modified as follows:

4.1.2 Water System Improvement Program

As discussed in Section 1.2, the proposed project, along with several other facility improvement projects, are components of the SFPUC's WSIP. The ~~WSIP Draft~~ Program EIR (~~Draft~~ PEIR), which was certified ~~was issued on June 29, 2007,~~ by the San Francisco Planning Commission on October 30, 2008, ~~Department to~~ addressed the potential environmental impacts of the WSIP ~~on a programmatic level~~ and evaluated regional water supply alternatives. Because the proposed project is a component of the WSIP the project would also contribute to the WSIP's ~~program level~~ water supply impacts.

The ~~WSIP Draft~~ PEIR analyzed~~s~~ potential water supply and system operations impacts (separate from environmental impacts associated with the facility improvements) within the following geographic regions: the Tuolumne River, Alameda Creek, Peninsula, and Westside Basin groundwater resources systems. The ~~WSIP Draft~~ PEIR also identified~~s~~ the cumulative effects of implementing the WSIP ~~water supply option~~ and system operations in combination with other past, present, and reasonably foreseeable future projects within each of these watersheds. It also discussed~~s~~ the potential effects of climate change and global warming on the regional water system.

The WSIP would result in changes in reservoir levels and associated changes in downstream flows in rivers and creeks in the three affected watersheds, potentially resulting in groundwater, water quality, fisheries, and terrestrial biological resources,. In the event that deliveries to customers exceed 265 mgd (average annual), streamflow changes in the Tuolumne River watershed could affect fisheries and terrestrial biological resources. In the Alameda Creek and Peninsula watersheds, the WSIP, which includes restoring the historical storage capacities of Calaveras and Lower Crystal Springs Reservoirs, could affect reservoir levels, downstream flows, fisheries, and terrestrial biological resources. In addition, similar to the originally proposed WSIP, the WSIP will develop groundwater supplies in the North Westside Groundwater Basin as well as a conjunctive-use program in the South Westside Groundwater Basin.

~~Because of the proposed increased Tuolumne River diversions and operational changes, the WSIP would result in changes in reservoir levels and associated changes in downstream flows in rivers or creeks in the three affected watersheds, potentially resulting in geomorphology, groundwater, water quality, fisheries, terrestrial biological resources, recreational, and visual impacts. In the Tuolumne River watershed, streamflow changes could affect downstream water supplies~~

~~and hydropower generation. In the Alameda Creek and Peninsula watersheds, the proposed WSIP would include restoring the historical storage capacities of Calaveras and Lower Crystal Springs Reservoirs, potentially affecting reservoir levels, downstream flows, fisheries, terrestrial biological resources, and visual resources. In addition, the proposed WSIP would develop groundwater supplies in the North Westside Groundwater Basin as well as a conjunctive use program in the South Westside Groundwater Basin.~~

~~The WSIP Draft PEIR identifies potential beneficial effects for energy resources (increased hydroelectric resource) and for fisheries in Calaveras Reservoir, Calaveras Creek, Alameda Creek below the convergence with Calaveras Creek, and San Antonio Reservoir.~~

As stated above, t~~T~~he proposed project is a component of the WSIP and therefore would contribute also to the ~~program-level~~ water supply impacts included in the tables below. Tables 4.1-1 through 4.1-4 summarize the WSIP water supply impacts and mitigation measures for each geographic region as analyzed in the ~~Draft~~ PEIR. Table 4.1-5 lists cumulative water supply impacts. Appendix B.1 presents the program-level environmental impact analysis and mitigation measures for the water supply and system operations associated with the ~~proposed~~ WSIP. In addition to water supply impacts and mitigation measures, the ~~WSIP Draft~~ PEIR provides a program-level analysis of the impacts associated with facility improvement projects, including construction and cumulative construction, and operation impacts. This EIR addresses the same issues as the ~~WSIP Draft~~ PEIR for the proposed project at a project-level detail.

Beginning on **Page 4.1-6** of the Draft EIR**,** portions of Table 4.1-1 have been revised as shown on the following pages:

Table 4.1-1
Summary of Water Supply Impacts and Mitigation Measures – Tuolumne River System and Downstream Water Bodies

Impact	Significance Determination					Mitigation Measures
	All Impacts (except Biological Resources)	Biological Resource Impacts				
		Sensitive Habitats	**Key Special-Status Species**	**Other Species of Concern**	**Common Habitats and Species**	
FISHERIES						
Impact 5.3.6-4: Effects on fishery resources along the Tuolumne River below La Grange Dam.	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less; PSM if deliveries exceed 265 mgd					**Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water:** The SFPUC will pursue a water transfer arrangement with MID/TID and/or other water agencies which would offset the WSIP's effects on water storage in Don Pedro Reservoir and minimize WSIP-induced changes in releases from La Grange Dam. **If Measure 5.3.6-4a proves to be infeasible, the SFPUC will implement Measure 5.3.6-4b. **Measure 5.3.6-4b, Fishery Habitat Enhancement:** The SFPUC will implement or fund one of two fishery habitat enhancement projects that are consistent with the Lower Tuolumne River Restoration Plan; augmentation of spawning gravel at five selected sites or the filling or isolation from the river of one of the existing inactive quarry pits.

Table 4.1-1
Summary of Water Supply Impacts and Mitigation Measures – Tuolumne River System and Downstream Water Bodies

TERRESTRIAL BIOLOGY						
Impact 5.3.7-6: Impacts on biological resources along the Tuolumne River below La Grange Dam.		LS when average annual deliveries from the watersheds are maintained at 265 mgd or less; PSM if deliveries exceed 265 mgd ~~PSM~~	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less; PSM if deliveries exceed 265 mgd ~~PSM~~	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less; PSM if deliveries exceed 265 mgd ~~PSM~~	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less; PSM if deliveries exceed 265 mgd ~~PSM~~	The SFPUC will implement Measures 5.3.6-4a or 5.3.7-6 to reduce adverse impacts on sensitive habitats, key special-status species, other species of concern, and common habitats and species to a less-than-significant level. **Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water** – see description above. **If Measure 5.3.6-4a proves to be infeasible, the SFPUC will implement Measure 5.3.7-6. **Measure 5.3.7-6, Lower Tuolumne River Riparian Habitat Enhancement:** Consistent with the Lower Tuolumne River Restoration Plan, the SFPUC will protect and enhance one mile of riparian vegetation within the contemporary floodplain.

Beginning on **Page 4.1-12** of the Draft EIR**,** portions of Table 4.1-2 have been revised as follows:

Table 4.1-2
Summary of Water Supply Impacts and Mitigation Measures – Alameda Creek Watershed

Impact	Significance Determination					Mitigation Measures
	All Impacts (except Biological Resources)	Biological Resource Impacts				
		Sensitive Habitats	Key Special Status-Species	Other Species of Concern	Common Habitats and Species	
RECREATION AND VISUAL

Impact 5.5.6-5: Impacts on biological resources along Pilarcitos Creek below Pilarcitos Reservoir.		LS~~PSM~~	LS	LS	LS	None required.~~The SFPUC will implement Measure 5.5.3-2 to reduce adverse impacts on sensitive habitats to a less-than-significant level.~~ **~~Measure 5.5.3-2, Revised Operations Plan for Pilarcitos Watershed Facilities~~** ~~– see description above.~~

4.2 Plans and Policies

Page 4.2-4 of the Draft EIR, after the paragraph (at the bottom of page 4.2-3) with the title "San Francisco Sustainability Plan" the following text has been inserted to incorporate recent planning efforts applicable to the project:

San Francisco Municipal Green Building Program

San Francisco's Green Building Program was founded in 1999 when the CCSF adopted the Resource Efficient Building Ordinance, which established green building standards for municipal buildings to increase energy efficiency, conserve CCSF finances, reduce the environmental impacts of demolition, construction, and operation of buildings, and create safe workplaces for CCSF employees and visitors. The ordinance created the inter-departmental Resource Efficient Building (REB) Task Force and charged the San Francisco Department of Environment with implementing the ordinance in partnership with the Department of Public Works and other REB Task Force departments. In 2004, amendments to Chapter 7 of the Environment Code set Leadership in Energy and Environmental Design (LEED) Silver Certification by the U.S. Building Council as the minimum environmental performance requirement for all municipal projects over 5,000 square feet. The REB Task Force assists City departments in compliance with the LEED Silver Certification requirement and helps to determine which projects are applicable for LEED ratings. For all municipal construction projects, including those projects that do not involve buildings and are not required to obtain LEED Silver Certification, the REB Task Force provides recommended best practices and sample specifications for building materials (e.g., recycled content of steel and concrete) (San Francisco Department of the Environment, 2004-2007).

Page 4.2-9 of the Draft EIR**,** after the paragraph under the title "San Francisco Sustainability Plan" the following text is added to address recent planning efforts applicable to the proposed project:

San Francisco Municipal Green Building Program

The San Francisco Municipal Green Building Program was developed for the purpose of improving the environmental performance of municipal buildings. The proposed project would be designed, constructed, and operated in accordance with the City's Green Building requirements. The SFPUC would complete and submit LEED checklists to the REB Task Force for the proposed project.

Page 4.2-11, under references for the Plans and Policies Section of the Draft EIR, the following text has been added as the second reference:

San Francisco Department of the Environment, San Francisco Municipal Green Building Report 2004-2007.

4.5 Hydrology and Water Quality

Page 4.5-3 of the Draft EIR, under the title "Groundwater" the second paragraph has been modified as follows:

> The San Joaquin River Hydrologic Region groundwater basin is the source for approximately 30 percent of agricultural and urban water usage annually in the region. Aquifers generally have thicknesses of several hundred feet in the hydrologic region and frequently necessitate well depths of up to 800 feet (DWR, 2003). Unless otherwise designated by the California Regional Water Quality Control Board, all groundwater in the Central Valley region is considered to be suitable or potentially suitable, at a minimum, for municipal and domestic supply, agricultural supply, industrial service supply, and industrial process supply.

4.6 Biological Resources

Page 4.6-7, in Table 4.6-1 of the Draft EIR a footnote has been deleted as USFWS no longer maintains a list of species under the designation of species of local concern.

TABLE 4.6-1

SPECIAL-STATUS PLANT SPECIES POTENTIALLY FOUND ONSITE

Plant Species Common Name	Legal Status Federal/State/CNPS	Potential for Occurrence Thomas Shaft	Potential for Occurrence Tesla Portal	Comments

Page 4.6-18 of the Draft EIR, the third full paragraph has been modified as follows:

> The state's authority to regulate activities in wetlands and waters at the project sites resides primarily with the California Regional Water Quality Control Board (RWQCB), which regulates construction in waters of the United States and waters of the state, including activities in wetlands, under both the Clean Water Act and the State of California's Porter-Cologne Water Quality Control Act.~~State Water Resources Control Board (SWRCB), which is delegated to the Regional Water Quality Control Board (RWQCB) for project review under Section 401 of the Clean Water Act and the Porter-Cologne Act. The SWRCB, acting through the nine Regional Water Quality Control Boards~~RWQCB, must certify that a USACOE permit action meets state water quality objectives (Section 401, Clean Water Act). In response to the SWANCC Supreme Court decision, the SWRCB issued a guidance for the protection of these waters previously within the USACOE's jurisdiction. The RWQCB now takes the lead role in regulating impacts to "isolated" waters that are no longer within federal jurisdiction. These waters are still considered "Waters of the State" pursuant to the Porter-Cologne Water Quality Control Act.

Page 4.6-25 of the Draft EIR, the third paragraph has been changed as follows:

> *Burrowing Owl*. The Tesla Portal project site supports suitable habitat (breeding and foraging) conditions for burrowing owls. Construction activities at the Tesla Portal site would temporarily reduce the amount of breeding and foraging habitat onsite and may result in take of this special-status species. Implementation of Mitigation Measures 4.6-3a, 4.6-3e, 4.6-3f, and 4.6-3g would reduce potential impacts to a less than significant level. Mitigation Measure 4.6-3a requires the SFPUC to implement a worker awareness program. Mitigation Measures 4.6-3e, 4.6-3f, and 4.6-3g require~~s~~ the SFPUC adopt all applicable ITMMs related to burrowing owls that have been identified in the SJMSCP. The ITMMs include preconstruction surveys~~,~~ and eviction of birds from the project site prior to ground disturbance or construction activities~~, the implementation of a 100-foot buffer until the burrow can be safely destroyed~~.

Page 4.6-26 of the Draft EIR, the paragraph under "Other Special-Status Raptor Species (Golden Eagle, Ferruginous Hawk and Prairie Falcon)" has been corrected as follows:

> *Other Special-Status Raptor Species (Golden Eagle, Ferruginous Hawk and Prairie Falcon).* Each special status raptor species is known or has potential to forage on both project sites. The proposed construction activities would temporarily impact potential foraging and breeding habitat of special-status raptor species. The temporary loss of the small amount of habitat (11.716 acres of grassland), from the project would not substantially affect overall habitat availability in the area or affect foraging behavior of these species or use of the surrounding area. Therefore, the temporary loss of a small amount of disturbed grassland habitat is considered negligible. Impacts would be reduced to less than significant with implementation of Mitigation Measures 4.6-3, 4.6-3i, 4.6-3~~4~~j, ~~and~~ 4.6-3~~4~~k, and 4.6-3l, requiring a workers awareness program and SJMSCP ITMMs for each species.

Page 4.6-26 of the Draft EIR, the paragraph under "Tricolored Blackbird" has been corrected as follows:

> *Tricolored Blackbird.* Foraging habitat for tricolored blackbirds is present at both project sites, and tricolored blackbirds are known to forage at Tesla Portal. Construction activities at the project sites would temporarily reduce the overall amount of tricolored blackbird foraging habitat onsite. However, given that suitable foraging habitat is so widespread in the region surrounding the project sites, impacts would be minimal and localized. Therefore, the temporary loss of foraging habitat for tricolored blackbirds is considered minor. Impacts would be ~~reduced to~~ less than significant.

4.7 Cultural Resources

Page 4.7-6 of the Draft EIR, per comment L-SFLPAB-03, the following text has been added to the second paragraph as follows:

> The Sierra Club, along with San Joaquin Valley farmers and the Spring Valley Water Company, contested the damming of the Tuolumne River. Opposition to construction of the Hetch Hetchy project came from a variety of interests. Understandably, the Spring Valley Water Company opposed this project, which effectively ended its role as the utility company supplying San Francisco with its municipal and domestic water (SFPUC, 1949). The Hetch Hetchy project was designed to transmit electrical power to San Francisco from a power plant at Moccasin. A politically charged conflict over this electric power and associated revenue pitted public power advocates against the privately financed electric power industry. Opposition came from electrical power generating companies like Pacific Gas and Electric Company (PG&E) and Great Western Power Company (GWP), two utilities that served San Francisco and the Bay Area at the time. These private power companies opposed the competing generation and sale of electricity by public agencies, which was a provision of the Raker Act. The City and County of San Francisco (CCSF) planned to acquire PG&E and GWP's distribution systems within its service area, but between 1927 and 1941 the public consistently rejected bond issues required to fund their acquisition; allegedly, this opposition to the bond measures was largely funded by PG&E (Hundley, 1992; Sayles, 1985). The CCSF's agreements to have PG&E (which had acquired GWP in the 1930s) wheel its power through the company's existing transmission and distribution systems for delivery to San Francisco agencies, and its purchase of city power for resale, caused a longstanding controversy between the federal government, public power advocates, and the CCSF.

Page 4.7-29, in response to comment L-SFLPAB-03, the following references have been added to the Cultural Resources section of the Draft EIR:

4.9 Air Quality

Page 4.9-22 of the Draft EIR**,** in response to comment L-SJVAPC-02, the first full paragraph is modified and Table 4.9-5 is inserted as follows:

Equipment exhaust emissions are generated from the combustion of fuels used for the operation of construction equipment. Fugitive dust emissions are generated by the suspension of particulate during earth-moving activities. Employee vehicle emissions and construction truck emissions are generated from the combustion of fuels and from the entrainment of road dust during travel along roadways on site and off site of the construction area. Asphalt paving emissions are generated from the evaporation of regulated volatiles, or diluents, used to liquefy asphalt cement. Reasonable worst-case uncontrolled construction emissions are summarized in Table 4.9-5.

TABLE 4.9-5
REASONABLE WORST-CASE ANNUAL UNCONTROLLED EMISSIONS AT THE TESLA PORTAL SITE DURING CONSTRUCTION (TONS PER YEAR)

Project Component	ROG	NO_x	CO	SO_2	PM_{10} (Dust)	PM_{10} (Exhaust)	PM_{10} Total	$PM_{2.5}$ (Dust)	$PM_{2.5}$ (Exhaust)	$PM_{2.5}$ Total	CO_2

Page 4.9-23, of the Draft EIR**,** in response to comment L-SJVAPC-02, after the first paragraph under the title Thomas Shaft, the following paragraph has been modified as follows:

> Details regarding the size, scope, and length of construction for the Thomas Shaft site are outlined in the project description (Chapter 3). Chapter 3 also details expected construction equipment that will be operational throughout build out. In general, construction at this location is anticipated to start July 2009 and last for approximately 6 months. The development footprint at the Thomas Shaft site is below the SJVAPCD's Rule 9510 threshold triggering the need for quantification and therefore emissions have not been calculated but are discussed qualitatively.

Page 4.9-23 of the Draft EIR, in response to comment L-SJVAPC-02, the tenth paragraph under Impact 4.9-1 is edited as follows:

> In accordance with the guidance outlined in the GAMAQI, the SFPUC would implement Mitigation Measures 4.9-1a and 4.9-1b, which require a host of actions that the SJVAPCD has determined will reduce fugitive dust (PM) emissions and equipment exhaust emissions. These measures include, but are not limited to: stabilization of dust emissions, hauling restrictions, track out restrictions, speed restrictions, idling restrictions, and activity management. See Section 5.2.5 for a specific listing of these actions. Implementation of fugitive dust control measures alone would result in a reduction in PM_{10} dust-related emissions by 40 percent and $PM_{2.5}$ emissions by 38 percent. Total PM_{10} and $PM_{2.5}$ emissions would be reduced by 7 and 2 percent, respectively.) related to construction emissions at the Tesla Portal site (URS, 2008). Implementation of ~~these mitigation~~ all of the measures included in Mitigation Measures 4.9-1a and 4.9-1b would reduce the potentially significant air quality impact associated with project construction emissions of criteria pollutants at the Tesla Portal site to less than significant.

Page 4.9-27, of the Draft EIR**,** in response to comment L-SJVAPC-02, the following text and table are inserted in the first paragraph:

> All operational exhaust emissions are generated from the combustion of fuels. Diesel tank emissions are generated from the displacement of volatile vapors during refilling and the evaporation of volatiles. Reasonable worst-case uncontrolled operations emissions are summarized in Table 4.9-6.

Table 4.9-6

Page 4.9-35, in response to comment L-SJVAPC-02, the Draft EIR is revised to include the following reference:

URS, 2008, San Joaquin Regional Water Quality Improvement Project Air Emissions Estimates. November 24, 2008.

4.11 Public Services and Utilities

Page 4.11-4 of the Draft EIR, the paragraph under the title "California Integrated Waste Management Act of 1989" is revised as follows to correct an editorial error:

California Integrated Waste Management Act of 1989

The California Integrated Waste Management (CIWM) Act of 1989 (Public Resources Code [PRC], Division 30), enacted through Assembly Bill (AB) 939 and modified by subsequent legislation, requires all California cities and counties to implement programs to reduce, recycle, and compost at least 50 percent of wastes by the year 2000 ~~beginning January 1, 2000, and divert at least 75 percent by 2010~~ (PRC Section 41780). The state determines compliance with this mandate (which includes both disposed and diverted waste) through a complex formula. This formula requires cities and counties to conduct empirical studies to establish a "base year" waste generation rate against which future diversion is measured. The actual determination of the diversion rate in subsequent years is arrived at through deduction, not direct measurement. Instead of counting the amount of material recycled and composted, the city or county tracks the amount of material disposed at landfills, then subtracts the disposed amount from the base year amount. The difference is assumed to be diverted (PRC Section 41780.2).

4.14 Energy Resources

Page 4.14-6 of the Draft EIR, the first paragraph under the title "Tesla Portal Site" has been revised as follows:

Tesla Portal Site

SFPUC Power Enterprise provides power to the SFPUC's regional water system facilities, which use an estimated total energy usage of approximately 44 million kWh per year. This annual estimate includes the Tesla Portal facilities, which has a current demand of approximately 175,000 kWh per year. Operation of the new facilities at the Tesla Portal site could substantially increase overall on-site energy consumption. The SFPUC estimates that, in total, operation of the proposed improvements at the Tesla Portal ~~facility~~ site would require approximately six million kWh per year. This estimate includes approximately 1,800,000 kWh for operation of the three new buildings (UV building, Chemical Process building and Office/Control building), approximately 3,550,000 kWh for the UV reactors, and approximately 650,000 kWh for the proposed pumps).

Accounting for current energy use ~~This additional energy demand~~ at the Tesla Portal site ~~would~~, the project would result in a net increase of approximately 5,825,000 kWh, which represents roughly 13 percent of the regional water system's current annual energy use. ~~Under the significance criterion for energy, this additional energy demand represents the use of a large amount of energy, which is considered a potentially significant impact.~~ As described in the setting, the energy use by the regional water system is a fraction (less than three percent) of the long-term annual average energy production of the Hetch Hetchy system, and would remain at approximately three percent including the project's increased operational energy use.

Page 4.14-7 of the Draft EIR, the first paragraph has been changed as follows to correct an editorial error:

The project's energy impacts would be reduced to less than significant with implementation of the project design features, described above, and implementation of Mitigation Measure 4.14-1, which would ensure that energy efficient equipment is used in the proposed project at the Tesla Portal site ~~and the Thomas Shaft sites~~. It would also require the preparation of a repair and maintenance plan for each facility to minimize power use and the use of renewable energy, such as solar power, at the Tesla Treatment Facility.

Page 4.14-7 of the Draft EIR, the second paragraph has been deleted to correct an editorial error:

~~implement energy efficiency measures consistent with the *California Energy Action Plan II* priorities, and also requires the development and use of solar power at Tesla Treatment Facility, would reduce the project's energy impact to a less-than-significant level.~~

4.15 Cumulative Effects

Beginning on **Page 4.15-23** of the Draft EIR, the second paragraph under "Energy Resources" has been modified to correct an editorial error as follows:

The SFPUC estimates that, in total, the proposed improvements at the Tesla Portal ~~facility~~ site would require the use of approximately 6,000,000 kWh per year, an increase from the existing annual consumption of 175,000 kWh. ~~The additional demand generated by the improvements made to the Tesla Portal facility would increase the facility's annual usage by approximately 35 times over its existing annual consumption, which is approximately 175,000 kWh per year.~~ Operation of project facilities at Thomas Shaft would result in an annual energy demand of 110,800 kWh, an increase ~~of 40,000 kWh per year (or 36 percent)~~ from its current average annual consumption of 70,800 kWh. The additional energy demand would represent roughly 13 percent of the regional water system's current annual energy use of 44 million kWh per year. Additionally, the energy use by the regional water system is a fraction (less than 3 percent) of

the long-term annual average energy production of the Hetch Hetchy system, and would remain at approximately 3 percent, including the project's increased operational energy use. ~~Implementation of the proposed project (facilities at both Tesla Portal and Thomas Shaft) would result in a combined annual energy use increase in the SFPUC Power Enterprise's San Joaquin Region approximately 51 times above its current consumption level.~~

Page 4.15-24 of the Draft EIR, the beginning of the third paragraph has been clarified as follows:

Mitigation Measure 4.14-1 requires energy efficiency measures consistent with the *California Energy Action Plan II* priorities to be undertaken at both sites. Mitigation Measure 4.14-1 also requires preparation of a repair and maintenance plan for each facility to minimize power use and include the use of renewable energy at the Tesla Treatment Facility.

Chapter 5 Mitigation Measures

Page 5-2, part of Table 5-1 of the Draft EIR has been revised as follows to correct editorial errors:

Mitigation Measures (summarized here – refer to complete text in section below)	Tesla Treatment Facility (Tesla Portal Site)	Lawrence Livermore Water Quality Improvements (Thomas Shaft Site)
Section 4.6 Biological Resources		
Mitigation Measure 4.6-2 – Return Site to Pre-Construction Condition	X	~~X~~
Mitigation Measures 4.6-3e, 3f and 3g – Conduct Pre-Construction Surveys for Burrowing Owls	X	~~X~~
Mitigation Measure 4.6-3h – Conduct Pre-Construction Surveys for Swainson's Hawk	X	~~X~~

Page 5-4, Mitigation Measure 4.6-1a of the Draft EIR is revised in response to comment S-CDFG-04 as follows:

Participate in the SJMSCP

Mitigation Measure 4.6-1a: Prior to the commencement of construction activities, SFPUC shall coordinate with the Joint Powers Authority (JPA)/Technical Advisory Committee (TAC), implement relevant ITMMs for applicable species (as identified in Mitigation Measures 4.6-3b through 4.6-3l, below) and pay any necessary fees to fund offsite compensation under the terms of the SJMSCP to provide replacement values that are equal to that of the permanent loss of ~~0.308~~ 3.2 acres of California annual grasslands and 0.01 acre of ruderal/disturbed land, and temporary impacts to 11.72 acres of California annual grassland and 0.96 acre of ruderal/disturbed land ~~habitat values of the artificial wetland, the temporary loss of <0.001 acre of ephemeral drainage, the~~

~~temporary loss and permanent conversion of natural lands~~, and incidental take authorization for special-status species.

Page 5-6, the second paragraph of Mitigation Measure 4.6-3c of the Draft EIR has been changed in response to comment S-CDFG-09 as follows:

A qualified biologist with demonstrated experience in kit fox biology, identification, and survey techniques, shall conduct preconstruction surveys two calendar weeks to 30 calendar days prior to commencement of ground disturbance. Surveys shall be conducted by qualified biologists. When surveys identify potential dens (potential dens are defined as burrows at least four inches in diameter which open up within two feet), potential den entrances shall be dusted for three calendar days to register track of any San Joaquin kit fox present. If no San Joaquin kit fox activity is identified, potential dens may be destroyed.

Page 5-7, Mitigation Measures 4.6-3e, 4.6-3f, and 4.6-3g of the Draft EIR have been changed in response to comment S-CDFG-10 as follows:

Conduct Pre-Construction Surveys for Burrowing Owls

Mitigation Measure 4.6-3e: Breeding Season Surveys. ~~In January, and again no more than two weeks before construction, a survey for burrows and burrowing owls shall be conducted by a qualified biologist within 500 feet of the project (access permitting). The survey will conform to the protocol described by the California Burrowing Owl Consortium in the Burrowing Owl Survey Protocol and Mitigation Guidelines (California Burrowing Owl Consortium, 1993), which includes up to four surveys on different dates if there are suitable burrows present.~~

~~If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with the California Department of Fish and Game (CDFG), as to whether or not work will affect the occupied burrows or disrupt reproductive behavior.~~

~~If it is determined that construction will not affect occupied burrows or disrupt breeding behavior, construction will proceed without any restriction or mitigation measures.~~

~~If it is determined that construction will affect occupied burrows during August through February, the subject owls will be passively relocated from the occupied burrow(s) using one-way doors. There will be at least two unoccupied burrows suitable for burrowing owls within 300 feet of the occupied burrow before one-way doors are installed. Artificial burrows will be in place at least one week before one-way doors are installed on occupied burrows. One-way doors will be in place for a minimum of 48 hours before burrows are excavated.~~ Measures to

avoid and minimize impacts on the western burrowing owl will be implemented as described below:

- If project schedule permits, a qualified biologist will survey for burrows and burrowing owls during the breeding season (February 1 to August 31), immediately preceding construction. Surveys will be conducted within 500 feet of the project boundary (access permitting) in accordance with the California Burrowing Owl Consortium (1993) guidelines or as otherwise determined by CDFG. Burrows would be inspected for signs of owl activity (tracks, pellets, feathers, etc.). The locations of burrowing owl sightings, occupied burrows, and burrows with signs of owl activity will be marked on a map of the project area at a scale sufficient to accurately show the distance of active burrows to the limits of construction. Surveys will be conducted on at least four separate dates during the breeding season in areas where suitable burrows are present. If possible, surveys will be conducted during the peak of the burrowing owl breeding season, generally between April 15 and July 15.

- If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with CDFG, as to whether work will affect the occupied burrows or disrupt reproductive behavior.

- If it is determined that construction will not affect occupied burrows or disrupt breeding behavior, construction will proceed without any restrictions or mitigation measures.

Mitigation Measure 4.6-3f: Winter Surveys. ~~During the non-breeding season (September 1 through January 31) burrowing owls occupying the project site should be evicted from the project site by passive relocation as described in the CDFG's Staff Report on Burrowing Owls (CDFG, 1995).~~ Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below:

- If birds are not observed during breeding season surveys, or if breeding season surveys are infeasible due to project scheduling, or if construction will occur during the wintering season, a winter survey will be conducted to identify non-breeding residents of the project site. Winter surveys will be conducted within 500 feet of the project site (access permitting) or as otherwise determined by CDFG during the period when wintering owls are most likely to be present (December 1 to January 31). The locations of burrowing owl sightings, occupied burrows, and burrows with signs of owl activity will be marked on a map of the project area at a scale sufficient to accurately show the distance of active burrows to the limits of construction.

- If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with CDFG, as to whether or not work will affect the occupied burrows.

- If it is determined that construction will not affect occupied burrows, construction will proceed without any restrictions or mitigation measures.

- If it is determined that construction will affect occupied burrows, the subject owls will be passively relocated from the occupied burrow(s) using one-way doors prior to the onset of breeding season. Owls will be encouraged to relocate to alternate burrows that are at least 160 feet from the construction limits. One alternate natural or artificial burrow for each burrow excavated will be in place at least one week before one-way doors are installed on occupied burrows. One-way doors will be in place for a minimum of 48 hours before burrows are excavated.

Mitigation Measure 4.6-3g: Fall Surveys.~~During the breeding season (February 1 through August 31) occupied burrows shall not be disturbed and shall be provided with a 100-foot protective buffer until and unless the TAC, with the concurrence of the Permitting Agencies' representatives on the TAC; or unless a qualified biologist approved by the Permitting Agencies verifies through noninvasive means that either: 1) the birds have not begun egg laying, or 2) juveniles from the occupied burrows are foraging independently and are capable of independent survival. Once the fledglings are capable of independent survival, the burrow can be destroyed.~~ Measures to avoid and minimize impacts on the western burrowing owl will be implemented as described below:

- If surveys must be conducted between September 1 and November 30 (which is outside of the time windows specified above), a qualified biologist will conduct a survey for burrows and burrowing owls no more than thirty (30) days prior to ground-disturbing activity. If necessary, resident owls will be passively relocated from occupied burrows, as described above. If construction activities are still ongoing beyond November 30, then winter surveys will be conducted during December and January.

Page 5-8, Mitigation Measure 4.6-3h of the Draft EIR has been changed in response to comment S-CDFG-11 as follows:

Conduct Pre-Construction Surveys for Swainson's Hawk

Mitigation Measure 4.6-3h: A qualified biologist shall conduct a preconstruction survey for Swainson's hawk, prior to the commencement of any ground disturbing construction activities (e.g., grass/vegetation/brush/tree removal, soil excavation, grading, vehicle access, staging of materials or vehicles, large scale materials off-haul or delivery, construction of temporary or permanent access roads).

In the case that Swainson's hawks are found nesting in the area, the SFPUC will notify CDFG. At a minimum~~In addition,~~ the following mitigations regarding Swainson's hawk, as listed from the SJMSCP, will be implemented:

- If a nest tree becomes occupied during construction activities, then all construction activities shall remain a distance of two times the dripline of the tree, measured from the nest.

- If any nest trees need to be removed, they may be removed between September 1 and February 15, when the nests are unoccupied.

The following two measures will also be implemented:

- If any unoccupied nests are found during preconstruction surveys, these nests may be removed when the nests are unoccupied.

- If any occupied nests are found during preconstruction surveys, then all construction activities shall remain at a distance of ¼ mile (1,320 feet), unless CDFG agrees to other equally effective measures ~~are agreed to by CDFG~~ (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc).

Page 5-8, Mitigation Measure 4.6-3i of the Draft EIR has been changed in response to comment S-CDFG-12 as follows:

Implement Incidental Take Minimization Measures for White-Tailed Kite

Mitigation Measure 4.6-3i: SFPUC shall implement the ITMM identified for the white-tailed kite under the SJMSCP, which consists of the following:

- A qualified biologist shall conduct preconstruction surveys and investigate all potential nesting trees on the project site (e.g., especially tree tops 15-59 feet above the ground in oak, willow, eucalyptus, cottonwood, or other deciduous trees), during the nesting season (February 15 to September 15) whenever white-tailed kites are noted on site or within the vicinity of the project site during the nesting season.

- If the species is found nesting, a setback of 100 feet from nesting areas shall be established and maintained during the nesting season for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective measures ~~are agreed to by CDFG~~ (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc.) and CDFG shall be notified of the proposed buffer zone. This setback applies whenever construction or other ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.

Page 5-9, Mitigation Measure 4.6-3j of the Draft EIR has been changed in response to comment S-CDFG-13 as follows:

Implement Incidental Take Minimization Measures for California Horned Lark and Northern Harrier

Mitigation Measure 4.6-3j: SFPUC shall implement the ITMM identified for the California horned lark and northern harrier under the SJMSCP, which consists of the following:

- A qualified biologist shall conduct a preconstruction survey and investigate all potential nesting trees to determine the presence or absence of the species on the project site.

- If species are found, a setback of 500 feet from nesting areas shall be established and maintained during the nesting season (February 16 – August 31) for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective measures ~~are agreed to by CDFG~~ (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc.), or offsite compensation shall be provided, and CDFG shall be notified of the proposed buffer zone. If a setback is used, this setback would apply whenever construction or other ground-disturbing activities must begin during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.

Page 5-9, Mitigation Measure 4.6-3k of the Draft EIR has been changed in response to comment S-CDFG-14 as follows:

Conduct Pre-Construction Surveys for Golden Eagle

Mitigation Measure 4.6-3k: Prior to the start of construction, a qualified biologist shall conduct golden eagle surveys as required by the SJMSCP. Additionally, SFPUC shall implement the ITMM identified for the golden eagle under the SJMSCP, which consists of the following:

- When a site inspection indicates the presence of a nesting golden eagle, CDFG will be notified and a setback of 500 feet from the nesting area shall be established and maintained during the nesting season (normally approximately February 1 – June 30) for the period encompassing nest building and continuing until fledglings leave nests, unless CDFG agrees to other equally effective measures ~~are agreed to by CDFG~~ (e.g., monitor occupied nest during construction in the buffer zone, limit hours of construction, restrict construction activities, etc). This setback applies whenever construction or other ground-disturbing activities must begin

during the nesting season in the presence of nests which are known to be occupied. Setbacks shall be marked by brightly colored temporary fencing.

Page 5-9, Mitigation Measure 4.6-3l of the Draft EIR has been changed in response to comment S-CDFG-15 as follows:

Conduct Pre-Construction Surveys for Ferruginous Hawk and Prairie Falcon

Mitigation 4.6-3l: Prior to the start of construction, a qualified biologist shall conduct surveys for ferruginous hawk and prairie falcon as required by the SJMSCP. These species currently do not nest in San Joaquin County and are not expected to nest in the County over the life of the SJMSCP. Therefore, in the highly unlikely event that one of these species is found nesting on a project site, SFPUC shall notify CDFG of the proposed buffer zone and a setback of 500 feet from the nesting area shall be established and maintained for the period encompassing nest building and continuing until fledglings leave the nests, unless CDFG agrees to other equally effective measures. ITMMs shall be formulated prior to ground disturbance by the TAC and approved by the JPA with the concurrence of the Permitting Agencies' representatives on the TAC in accordance with the SJMSCP's Adaptive Management Plan. ITMMs may consist of preconstruction surveys, avoidance techniques, and buffer areas.

Starting on **Page 5-10**, Mitigation Measure 4.7-2a of the Draft EIR has been changed as follows:

Accidental Archaeological Discovery

Mitigation Measure 4.7-2a: SFPUC Standard Construction Measure #9 for cultural resources requires that construction activities be suspended immediately if there is any indication of an archaeological resource.

To avoid any potential adverse effect from the proposed project on accidentally discovered buried or submerged historical resources as defined in CEQA Guidelines Section 15064.5(a)(c), the SFPUC shall distribute the Planning Department archaeological resource "ALERT" sheet to the project prime contractor; to any project subcontractor (including firms specializing in demolition, excavation, grading, foundation, pile driving, etc.); or utilities firm involved in soil disturbing activities within the project site. Prior to any soil disturbing activities being undertaken, each contractor is responsible for ensuring that the "ALERT" sheet is circulated to all field personnel including, machine operators, field crew, pile drivers, supervisory personnel, etc. The SFPUC shall provide the Environmental Review Officer (ERO) with a signed affidavit from the responsible parties (prime contractor, subcontractor(s), and utilities firm) ~~to the ERO~~ confirming that all field personnel have received copies of the "ALERT" sheet.

Should any indication of an archaeological resource be encountered during any soils disturbing activity of the project, the contractor and/or the SFPUC will immediately notify the ERO and will immediately suspend any soils disturbing activities within 100 feet of the discovery until the ERO has determined what additional measures should be undertaken.

If the ERO determines that an archeological resource may be present within the project site, the SFPUC shall retain the services of a qualified archeological consultant. The archeological consultant shall advise the ERO as to whether the discovery is an archeological resource that ~~,~~ retains sufficient integrity, and is of potential scientific/historical/cultural significance. If an archeological resource is present, the archeological consultant shall identify and evaluate the archeological resource. The archeological consultant shall make a recommendation as to what action, if any, is warranted. Based on this information, the ERO may require, if warranted, specific additional measures to be implemented by the SFPUC.

Measures might include: preservation in situ of the archeological resource; an archaeological monitoring program; or an archeological ~~testing~~ evaluation program. If an archeological monitoring program or archeological ~~testing~~ evaluation program is required, it shall be consistent with the MEA WSIP Archaeological Guidance (San Francisco Planning Department, 2008) ~~guidelines~~ for such programs. The ERO may also require that the SFPUC immediately implement a site security program if the archeological resource is at risk from vandalism, looting, or other damaging actions.

The project archeological consultant shall submit an accidental discovery Archaeological Data Recovery Report (ADRR) to the ERO, which, in addition to the usual contents of the ADRR, includes an evaluation of ~~the appropriate report(s) in accordance with the MEA WSIP Projects Archaeological Guidance series that evaluates~~ the historical significance of any discovered archeological resource, as well as describing ~~and describes~~ the archeological and historical research methods employed in the archeological monitoring/data recovery program(s) undertaken, and presenting, analyzing, and interpreting the recovered data.. Information that may put at risk any archeological resource shall be provided in a separate removable insert within the final report.

Once approved by the ERO, copies of the ADRR ~~report(s)~~ shall be distributed as follows: the relevant California Historical Resources Information System Information Center shall receive one (1) copy and the ERO shall receive a copy of the transmittal letter of the ADRR ~~report~~ to the Information Center. The MEA shall receive three copies of the ADRR ~~each report~~ along with copies of any formal site recordation forms (CA DPR 523 series) and/or documentation for nomination to the National Register of Historic Places/California Register of Historical Resources. The SFPUC shall receive copies of the ADRR~~report(s) as requested~~ in the number requested. In instances of high public interest in or the

high interpretive value of the resource, the ERO may require a different final report content, format, and distribution than that presented above.

Page 5-11, Mitigation Measure 4.7-2b of the Draft EIR has been changed as follows:

Treatment of Human Remains

Mitigation Measure 4.7-2b: The treatment of human remains and of associated or unassociated funerary objects discovered during any soils disturbing activity shall comply with applicable State laws. This shall include immediate notification of the San Joaquin County Coroner and in the event of the coroner's determination that the human remains are Native American ~~remains~~, notification of the California State Native American Heritage Commission (NAHC) who shall appoint a Most Likely Descendant (MLD) (Public Resources Code Section 5097.98). The archaeological consultant, SFPUC, and MLD shall make all reasonable efforts to develop an agreement for the treatment of, with appropriate dignity, human remains and associated or unassociated funerary objects (CEQA Guidelines Section 15064.5(~~e~~d)). The agreement should take into consideration the appropriate excavation, removal, recordation, analysis, custodianship, curation, and final disposition of the human remains and associated or unassociated funerary objects. California Public Resources Code ~~State law~~ allows 24 hours to reach agreement on these matters. If the MLD~~s~~ and the other parties do not agree on the reburial method, the project will follow Section 5097.98(b) of the California Public ~~r~~Resources ~~c~~Code which states, "the landowner or his or her authorized representative shall reinter the human remains and items associated with Native American burials with appropriate dignity on the property in a location not subject to further subsurface disturbance."

Page 5-14, under Mitigation Measure 4.9-1b of the Draft EIR the following text of the mitigation measure is changed to be consistent with the text contained within the air quality section:

SJVAPCD Exhaust Control Measures

Mitigation Measure 4.9-1b: The following mitigation measures will be implemented during construction of the proposed project to reduce exhaust emissions:

(1) SJVAPCD Guide to Assessing and Mitigating Air Quality Impacts Mitigation Measures:

To limit exhaust emissions within the San Joaquin Region, the SJVAPCD specifies the following exhaust controls for heavy-duty equipment (scrapers, graders, trenchers, earthmovers, etc.). The SFPUC will include these measures, where feasible and applicable, in contract specifications:

- Idling time (e.g., ~~10~~5-minute maximum) shall be minimized.

- The hours of operation of heavy-duty equipment and/or the amount of equipment in use shall be limited.

- Activity management (e.g., rescheduling activities to reduce short-term impacts) shall be implemented.

Page 5-16, the following reference has been added to the Mitigation Measures section of the Draft EIR:

> San Francisco Planning Department, MEA WSIP Projects Archaeological Guidance Documents. 2008.

Chapter 6 Growth-Inducement Potential and Indirect Effects of Growth

Page 6-1 of the Draft EIR, under the second paragraph the two proceeding paragraphs have been modified as follows:

> The ~~Draft~~ PEIR on the San Francisco Public Utilities Commission's (SFPUC's) Water System Improvement Program (WSIP) concluded that the WSIP as a whole would support growth in the existing SFPUC service area. And, as explained in Chapter 3, Project Description, the proposed project is a component of the WSIP and thus contributes to its indirect growth inducement effect. By providing additional water supply to SFPUC customers within the SFPUC service area, the WSIP, and the proposed project, as part of the WSIP, would have an indirect growth-inducing effect according to the CEQA definition above.[2]
>
> Implementation of the WSIP would meet customer purchase requests through the year 2018~~2030~~, as discussed in the ~~Draft~~ PEIR. Meeting additional purchase requests would provide water to serve additional residential and business customers in the existing SFPUC service area.

Beginning at the top of **Page 6-2** of the Draft EIR the text has been modified as follows:

> below, Indirect Effects of Growth). The SFPUC service area spans seven counties—Tuolumne, Stanislaus, San Joaquin, Alameda, Santa Clara, San Mateo, and San Francisco. ~~The Association of Bay Area Governments (ABAG) is the agency responsible for providing regional growth projections for the San Francisco Bay Area, which covers the majority of the SFPUC service area. Although the proposed project is outside of the Bay Area, the ABAG growth projections, along with other published sources (such as Urban Water Management Plans), are discussed below because of their relevance to the SFPUC service area.~~
>
> The project is primarily proposed to ensure that the SFPUC maintains high-quality water that meets or exceeds regulatory standards for drinking water into

the future and, therefore, would contribute to the WSIP's water quality goal. The proposed project would also contribute to the WSIP's seismic reliability goal by reducing the system's vulnerability to earthquakes through the construction of a new chlorination facility at the Tesla Portal site designed to meet current seismic standards, and designed to treat additional water supply up to 313 million gallons per day consistent with the WSIP ~~Draft PEIR~~. Because the proposed project is part of the WSIP, the project would also contribute indirectly to the WSIP's growth inducement impact.

Page 6-2 of the Draft EIR, the following text has been added preceding the last sentence on the page:

By removing the lack of a reliable water supply and water system (as one potential obstacle to growth within the SFPUC service area) and providing and assisting in development of additional water supply sources, such as recycled water and groundwater projects as well as promotion of more efficient use of water through conservation measures, the WSIP would have an indirect growth-inducing effect according to the CEQA definition above. The WSIP would support growth in the SFPUC service area through 2018, although it appears that some growth would occur irrespective of the WSIP due to increased water delivery efficiencies (e.g., plumbing code changes), conservation, and other water supply sources. Growth would in turn result in indirect effects. In most cases, the effects of population and employment growth have been identified and addressed in the EIRs for the general plans and associated area plans and specific plans adopted by the jurisdictions in the service area. Some of the identified indirect effects of growth are potentially significant and unavoidable; others are significant but can be mitigated.

Potentially significant and unavoidable impacts as a result of growth in the SFPUC service area could occur in the following areas: traffic congestion, air pollution, traffic noise, construction noise, increased demand for public schools and other public services, loss of recreational opportunities and impacts on visual quality resulting from the loss of open space, cumulative effects on over-utilized parks, loss of wildlife habitat and wetlands and impacts on other biological resources, cumulative impacts on cultural resources, increased flooding potential, increased urban runoff pollutants, seismic hazards, induced population growth, failure to meet housing demand for projected population growth, exposure of new development to contaminated soil or groundwater, insufficient water supply, insufficient wastewater disposal capacity, loss of agricultural resources, land use conflicts, conflicts with existing land use plans or policies, and changes in density, scale, and character of an area.

The adopted WSIP would have growth-inducement potential through 2018 because the SFPUC (with the cooperation of the wholesale customers) would provide the additional water supply to meet purchase requests though 2018. The

WSIP would support much of the growth through 2018 in the jurisdictions served by the SFPUC regional water system. In general, development that was planned and approved through the general plan process in the SFPUC service area would have environmental impacts. The environmental consequences of this planned growth have been largely addressed in local plans and the associated CEQA review as well as in other, project-specific documentation. In a number of jurisdictions, negative declarations or mitigated negative declarations were prepared for general plans and related planning documents that were found not to have significant environmental effects.

With the exception of the No Purchase Request Alternative, all of the alternatives analyzed in the PEIR contribute in similar ways to growth inducement impacts, since each of the alternatives provides different ways of meeting future water supply demand as one of the WSIP objectives. It is also likely that the water customers would find alternate sources of water to meet future demand under the alternatives that are not effective in meeting demand like the Aggressive Conservation and Recycling Alternative. Under this scenario, the alternative itself may not be growth-inducing, but growth could still occur. No mitigation measures were proposed for implementation by the SFPUC that could substantially decrease or eliminate growth-inducing impacts because the SFPUC does not have control over the decisions that each local agency will make with respect to growth in their jurisdictions. Individual agencies' general plans and environmental documents contain actions, limitations and mitigation measures that will be implemented in the individual jurisdictions with local development project or program approvals. These types of mitigation measures were identified in the PEIR (see Appendix B of this Draft EIR.)

Page 6-2 of the Draft EIR, the last sentence on the page has been modified as follows:

To assess the growth inducement potential of the WSIP and characterize the secondary effects of growth, the ~~Draft~~ PEIR investigated the following questions:

Beginning on **Page 6-4** of the Draft EIR, beginning with "6.2 Summary of Conclusions" on Page 6-4 and ending with "6.2.4 Indirect Effects of Growth" on Page 6-6, the text has been modified as follows:

6.2 Summary of Conclusions

~~The following bullet items highlight the key findings of the growth inducement analysis included in this Draft EIR as Appendix B.2.~~

~~6.2.1 Service Area Characteristics, Growth Trends and Policies~~

A review of historical growth trends of a selection of jurisdictions in the service area, based primarily on information in general plans and Bay Area Water Supply and Conservation Association profiles, shows that:

- Cities in the service area are largely urbanized, most having experienced their most rapid growth in the postwar decades through the 1970s.
- Milpitas and East Palo Alto have experienced high rates of growth more recently.
- San Francisco's population fluctuated somewhat but on average has been essentially stable over the past 50 years.
- Many jurisdictions cannot grow laterally and their general plans include policies to manage growth; many general plans identify strategies consistent with "smart growth" principles, such as encouraging infill development and the redevelopment of previously developed areas, as means to accommodate future growth.
- The SFPUC's wholesale customers vary widely, in a variety of ways: by size, overall demand projected for 2030, the change that the 2030 demand represents in absolute terms and as a percentage of 2001 demand, and the degree to which the customers depend on the SFPUC for their water supply. As such, the WSIP would remove growth obstacles to varying degrees within the service area.

As stated above, the complete growth inducement analysis is included in this Draft EIR as Appendix B.2.

~~6.2.2 Growth Assumptions Used to Develop 2030 Water Demand and Purchase Requests Compared with ABAG Growth Projections~~

~~As discussed in Sections 7.2.2 through 7.3.2 in Appendix B.2, each SFPUC wholesale customer selected a published source for growth projections to use in developing its service area's projections for total water demand in 2030 and subsequently identified its estimated level of water purchase in 2030 from the SFPUC. The majority of customers (about two-thirds) selected the most current ABAG projections available at the time (*Projections 2002*); while the others (about one third) selected other published sources (such as Urban Water Management Plans) for their population growth projections. *Projections 2002* was used by for almost all of the employment growth projections. These customer-selected growth projections were compared to ABAG's most recent projections series, *Projections 2005*.~~

- The growth assumptions used to derive the 2030 water demand estimates and subsequently the water customer purchase requests from the SFPUC are generally consistent with the most recent ABAG projections for jurisdictions in the service area. For the most part, the analysis demonstrates that, compared to the forecasts in ABAG's *Projections 2005*, the customer-selected projections used to derive water demand in the wholesale and retail service areas indicate:

  - Somewhat less growth in employment and population (fewer added jobs and residents) through 2030, due largely to the expectation of more existing jobs in the area in 2005 than ABAG's *Projections 2005* estimates

  - More total employment in 2030 than ABAG's *Projections 2005* projects by about 5 percent overall

  - Less total population in 2025 and 2030 by about 5 percent overall

- The growth that would be supported by the WSIP is generally consistent with current ABAG 2005 projections for jurisdictions in the service area. Because of differences in geographic area covered by most of the water customers and the jurisdictions they serve, they do not match exactly, and a few cannot be reasonably compared.

6.2.3 Growth Assumptions Used to Develop 2030 Water Demand and Purchase Requests Compared to General Plan Growth Projections

As discussed in Section 7.3.3 in Appendix B.2, the existing, adopted general plans for cities within the SFPUC wholesale customer service area and for San Francisco were reviewed to compare the level of growth projected in these land use plans with that reflected in the growth assumptions used in the WSIP planning studies. The key findings of this review are:

- The horizon years for projections in the general plans considered in the analysis vary from 2005 to 2025; none of the plans extend out to 2030, which is the WSIP planning horizon. Due to the WSIP's longer planning horizon, in some areas the WSIP could support a degree of growth that has not been addressed in adopted land use plans.

- Comparison of the growth assumed in the development of the WSIP demand projections with growth forecasted in locally adopted land use plans indicates that much of the WSIP-related growth has been addressed in the adopted plans. A comparison of general plan projections with those selected by the water customers shows that:

- ~~The population growth assumed in the demand projections for most (17 of 20) of the water customers for which comparable general plan projections are available is similar to the growth anticipated in the general plans of the cities served by them.~~

- ~~The employment growth assumed in the demand projections for most (11 of 16) of the water customers for which comparable general plan projections are available are generally consistent with (within 20 percent of) the employment growth anticipated in the general plans of the cities served by them. This general consistency was found despite the extraordinary job growth that occurred as a result of the economic boom in the 1990s, which was substantially reflected in employment projections used for the water demand projections (*Projections 2002*) but was not reflected to the same degree in earlier projections series used for many of the general plan employment estimates.~~

- ~~The employment growth assumed for four wholesale customers is substantially greater (between 20 and 70 percent greater) than the growth anticipated in the respective general plans, due to the economic boom that occurred in the 1990s in the Bay Area, which affected various jurisdictions differently. This difference in growth assumptions suggests that a degree of commercial and industrial growth assumed in the demand projections is not fully addressed in the respective general plans.~~

- ~~The general plans of jurisdictions in the SFPUC service area vary substantially in age, whereas the ABAG projections are updated every two years.~~

6.2.41 Indirect Effects of Growth

Chapter 7 Significant Environmental Effects That Cannot Be Avoided if the Proposed Project Is Implemented

Page 7-1 of the Draft EIR, the second paragraph has been modified as follows:

> However, as discussed in this Draft EIR, ~~Chapter 6, Growth Inducement,~~ the proposed project is one of several improvement projects that comprise the San Francisco Public Utilities~~y~~ Commission (SFPUC) Water System Improvement Program (WSIP)~~, and implementation of the WSIP would support growth in the SFPUC service area, thereby contributing indirectly, to environmental impacts caused by that growth. Because the proposed project is part of the WSIP and would contribute to the WSIP's growth inducement impact, the project therefore would contribute to the significant and unavoidable program-level impacts associated with growth inducement.~~ Insofar as the proposed project is a component of the WSIP, it would contribute to the WSIP's unavoidable water supply and growth-inducement impacts, as follows:

Potentially Significant and Unavoidable WSIP Water Supply Impacts

- Fisheries (Upper and Lower Crystal Springs Reservoir): Effects in the Peninsula watershed on fishery resources in Crystal Springs Reservoir in San Mateo County; and

- Growth Inducement: Indirect growth-inducement impacts in the SFPUC service area.

Significant and Unavoidable WSIP Water Supply Impacts

- Streamflow (Alameda Creek below Alameda Creek Diversion Dam): Effects on stream flow in Alameda Creek between the diversion dam and the confluence with Calaveras Creek.

Chapter 9 CEQA Alternatives

Page 9-2 of the Draft EIR, the first paragraph has been modified as follows:

The proposed project is a component of the San Francisco Public Utilities Commission's (SFPUC) Water System Improvement Program (WSIP). As required by CEQA, the ~~Draft~~ Program EIR (~~Draft~~ PEIR) ~~on the WSIP~~ evaluated a range of alternatives to the WSIP. This proposed project, which is listed as three separate projects in the ~~WSIP Draft~~ PEIR: the Tesla Portal Disinfection Facility, the Hetch Hetchy Advanced Disinfection, and the Lawrence Livermore Supply Improvements, is included in all of the WSIP alternatives. The ~~WSIP Draft~~ PEIR No Program Alternative includes the Hetch Hetchy Advanced Disinfection as it is an improvement to comply with the new federal drinking water regulatory requirements contained in the Long Term 2 Enhanced Surface Water Treatment Rule. The remainder of the proposed project evaluated in this EIR is not included in the ~~WSIP Draft~~ PEIR No Program Alternative. The WSIP alternatives are summarized in Section 9.2 and are analyzed in detail in Chapter 9 of the ~~Draft~~ PEIR, which is included in Appendix B.3 of this document.

Page 9-2 of the Draft EIR, under "9.2 WSIP Alternative" the text has been modified as follows:

9.2 WSIP Alternatives

The ~~WSIP Draft~~ PEIR evaluated~~s~~ seven alternatives to the ~~proposed~~ WSIP, summarized below, because of their apparent ability to meet most of the WSIP's goals, their ability to reduce one or more of the potentially significant impacts associated with program implementation, their potential feasibility, and their collective ability to provide a reasonable range of alternatives to foster informed decision-making and public participation. Analysis of the No Program Alternative is included as required by CEQA. Appendix B.3 includes more detailed descriptions of these WSIP alternatives, and also presents the associated program-level environmental analysis.

The WSIP that was ultimately adopted by the SFPUC incorporates elements of three alternatives to the originally proposed WSIP: the No Purchase Request Alternative, the Aggressive Conservation/Water Recycling and Groundwater Alternative, and the Modified WSIP Alternative.

Page 9-3 of the Draft EIR, under "9.2.3 Aggressive Conservation/Water Recycling and Local Groundwater Alternative" the text has been modified as follows:

9.2.3 Aggressive Conservation/Water Recycling and Local Groundwater Alternative

Under the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, the SFPUC would implement all of the ~~proposed~~ WSIP facility improvement projects, but would endeavor to serve the projected increase in customer purchase requests through 2030 only through additional conservation, water recycling, and local groundwater projects. Under this Alternative the SFPUC would have to either: (a) limit future customer purchase deliveries to the level that can be met, short of 2030 requests (approximately 294 mgd instead of 300 mgd average annual) and increase the level of rationing to 25 percent or more during droughts, or (b) provide a supplemental supply to make up the delivery shortfall to meet the 300 mgd.

Page 9-3 of the Draft EIR, under "9.2.4 Lower Tuolumne River Diversion Alternative" the text has been modified as follows:

9.2.4 Lower Tuolumne River Diversion Alternative

Under the Lower Tuolumne River Diversion Alternative, the SFPUC would implement all of the proposed facility improvement projects and would serve the projected increase in customer purchase requests through 2030 through diversions from the lower Tuolumne River near its confluence with the San Joaquin River, assuming an agreement can be reached with the Turlock Irrigation District and the Modesto Irrigation District. This alternative would include construction and operation of additional conveyance and treatment facilities to divert, transport, treat, and blend the new supply into the regional water system.

Page 9-3 of the Draft EIR, under "9.2.7 Modified WSIP Alternative" the text has been modified as follows:

9.2.7 Modified WSIP Alternative

Under the Modified WSIP Alternative, the SFPUC would implement all of the proposed facility improvement projects, but would modify proposed system operations to minimize environmental effects. This alternative would include the implementation of key mitigation measures identified in the ~~Draft~~ PEIR.

Page 9-4 of the Draft EIR, under "9.2.8 Comparison of Alternatives to the Proposed WSIP" the text has been modified as follows:

9.2.8 Comparison of Alternatives to the ~~Proposed~~ WSIP

The seven ~~eight~~ alternatives analyzed in the ~~Draft~~ PEIR would have varying abilities to meet the goals and objectives established by the SFPUC for the WSIP and would have a wide range of additional environmental effects. The No Program, No Purchase Request Increase, and Aggressive Conservation/Water Recycling and Local Groundwater Alternatives would fail to meet one or more key program objectives, while the Lower Tuolumne River Diversion, Year-round Desalination at Oceanside, Regional Desalination for Drought, and Modified WSIP Alternatives would meet most of the basic program objectives. The SFPUC found that many of the Alternatives would have greater environmental impacts than the adopted WSIP. (See SFPUC Resolution No. 08-0200.)

Page 9-10 of the Draft EIR, under "Conclusions" the text has been modified as follows:

Conclusions

The No Project Alternative (Status Quo) would reduce potentially significant, but mitigable direct impacts associated with construction and operation of the proposed project, including, alteration of views as viewed from a scenic route and nighttime light and glare at the Tesla Portal site, impacts on biological and cultural resources, and noise, and air quality impacts. This alternative would also avoid the project's contribution to the SFPUC's ~~Water System Improvement Program's (~~WSIP~~)~~ potentially significant and unavoidable program-level impacts associated with growth inducement. However, under the No Project Alternative (Status Quo), if existing disinfection facilities at the Tesla Portal site were to become damaged during a seismic event, impacts similar to the proposed project, or potentially greater since facility replacement would occur during emergency conditions, would be expected. Damage to existing disinfection facilities resulting from a seismic event could also affect the SFPUC's ability to deliver water to meet demands in the Sunol Valley, Bay Division, Peninsula, and San Francisco sub-regions of its regional water service area. The No Project Alternative (Status Quo) would not meet any of the project objectives and would not meet contractual obligations to LLNL. Furthermore, under the No Project Alternative (Status Quo), the SFPUC would not comply with LT2ESWTR.[1]

Page 9-14 of the Draft EIR, under "Conclusions" the text has been modified as follows:

Conclusions

The No Project Alternative (Compliance with Safe Drinking Water Regulations) would reduce potentially significant but mitigable direct impacts associated with construction and operation of the proposed project since fewer facilities would be

built. These reduced impacts include alteration of views as viewed from a scenic route and nighttime light and glare at the Tesla Portal site, impacts on biological and cultural resources, and noise, and air quality impacts. This alternative would also avoid the project's contribution to the SFPUC's WSIP's potentially significant and unavoidable program-level impacts associated with growth inducement. However, under this alternative, if existing disinfection facilities at the Tesla Portal site were damaged during a seismic event, impacts similar to the proposed project, or potentially greater, since facility replacement would occur during emergency conditions, would be expected. Damage to existing disinfection facilities resulting from a seismic event could also affect the SFPUC's ability to deliver water to meet demands in the Sunol Valley, Bay Division, Peninsula, and San Francisco sub-regions of its regional water service area. This alternative would construct new water treatment facilities, and therefore, would meet the project objective related to compliance with LT2ESWTR. However, it would not meet contractual obligations to LLNL and it would not seismically upgrade existing facilities.

Page 9-16 of the Draft EIR, under "Conclusions" the text has been modified as follows:

Conclusion

Alternative 3: Continue Water Source to Artificial Wetland at Tesla Portal ~~S~~site would meet all of the project objectives and, therefore, would be expected to have similar growth inducement impacts compared to the proposed project. This alternative would contribute to the SFPUC's WSIP's potentially significant and unavoidable program-level impacts associated with growth inducement. This alternative would avoid impacts associated with permanent loss of 0.308 acre of artificial wetland at the Tesla Portal site and the associated loss of habitat value to dependent plant and wildlife species that are identified as potentially significant but mitigable under the proposed project. Other potentially significant but mitigable biological resources impacts during project construction would be the same as the proposed project under this alternative. This alternative would implement the Lawrence Livermore Water Quality Improvements at the Thomas Shaft site as described in Chapter 3. Therefore, the impact analysis and conclusions presented in Chapter 4 related to the Thomas Shaft site would be the same under this alternative, and are not discussed further in this section. Given that this alternative would implement all the same improvements as the project (excluding discontinuing the permanent, year round water supply to the artificial wetland at the Tesla Portal site), its potential impacts would be the same as the project's potential impacts for the following resource areas:

Page 9-18 of the Draft EIR, under "Conclusions" the text has been modified as follows:

Conclusion

Alternative 4: Combine Office/Control Building and UV Building at Tesla Portal ~~S~~site would meet all of the project objectives and, therefore, would be expected to have similar growth inducement impacts compared to the proposed project. This alternative would contribute to the SFPUC's WSIP's potentially significant and unavoidable program-level impacts associated with growth inducement. This alternative would reduce the severity of impacts associated with biological and cultural resources, and air quality in the proposed project area; these impacts would remain potentially significant, but mitigable as they are under the proposed project. Additionally, this alternative would reduce the severity of the project's erosion and sedimentation potential (a less than significant impact). It would also slightly increase the amount of land available for cattle grazing at the Tesla Portal site. However, this alternative could result in greater visual impacts because of the increased building height. Because this alternative would implement all project features identified in the project description in Chapter 3 with the exception that it would reduce the development footprint of the project, it would be expected to result in similar impacts as the project for the following resource areas:

Page 9-22 of the Draft EIR, under "Conclusions" the text has been modified as follows:

Conclusion

Alternative 5: Retrofit of Existing Tesla Portal Hypochlorite Station Building would be expected to have similar growth inducement impacts compared to the proposed project, and would contribute to the SFPUC's WSIP's potentially significant and unavoidable program-level impacts associated with growth inducement. This alternative site configuration would reduce the severity of some of the impacts associated with the proposed project but would not reduce the need for mitigation or change the determinations of significant but mitigable impacts. It would reduce the amount of erosion, dust, and temporary California annual grassland and ruderal/disturbed habitat disturbance during construction. During operations, it would have reduced visual, erosion, and water quality impacts; would not convert as much special-status wildlife foraging and/or breeding habitat as the project; and would increase the agricultural productivity potential (grazing) of the site relative to the proposed project. This alternative would not be able to accommodate the pH adjustment equipment and, therefore, that project objective would not be met, and a building for this equipment may be needed in the future. Furthermore, this alternative would not have the reliability and performance capability of a new facility. Due to the minor changes associated with this alternative compared to the proposed project, it would be expected to result in similar impacts as the project for the following resource areas:

Appendix B WSIP PEIR Reference Chapters

Appendix B of the Draft EIR has been revised to include the following introduction as well as additional chapters from the WSIP PEIR; including Chapter 13, Chapter 14, portions of Chapter 16, and Appendix O:

Overview and Introduction

As discussed in this Draft Environmental Impact Report (Draft EIR), the proposed project is part of the San Francisco Public Utilities Commission's (SFPUC) Water System Improvement Program (WSIP). The San Francisco Planning Department prepared a Draft Program Environmental Impact Report (PEIR) on the WSIP, which was published on June 29, 2007. After responding to public comments on the Draft PEIR, the Final PEIR was certified by the San Francisco Planning Commission on October 30, 2007 (Motion No. 17734). On that same day, the revised WSIP (known as the "Phased WSIP Variant" in the Final PEIR) was adopted by the SFPUC (Resolution 08-0200).

Because the proposed project is a component of the WSIP, it would contribute to the impacts that would occur with implementation of the WSIP's water supply strategy, including its growth-inducement impacts. These impacts are summarized in the main body of this Draft EIR in the Executive Summary and in Section 4.1, Approach to Analysis, of this Draft EIR. This appendix supplements the WSIP impact summaries by including the actual text from the Draft and Final PEIR on the WSIP's water supply impacts.

Due to the timing of publication of this Draft EIR, certification of the Final PEIR, and adoption of the WSIP, this appendix was assembled to present information on the impacts of the WSIP's water supply strategy and also to correct some of this information in response to comments on the Draft PEIR, as set forth in the Final PEIR. Specifically, this appendix includes the actual text in the Draft and Final PEIR on the originally proposed and the revised, adopted WSIP along with other information and text changes from the Final PEIR relevant to the WSIP's water supply strategy as it relates to the proposed project.

Contents of this Appendix

Text from the Draft PEIR on the WSIP

This appendix contains the following text on the WSIP's water supply impacts from the Draft PEIR:

- **Chapter 5 (Volume 3 of the PEIR):** This chapter evaluates the potential environmental impacts of the WSIP's water supply strategy and regional water system operations. The impact discussion is organized by watershed and related drainages and reservoirs.

- **Chapter 7 (Volume 4 of the PEIR):** This chapter analyzes the WSIP's growth inducement potential and associated secondary effects of growth impacts.

- **Chapter 9 (Volume 4 of the PEIR):** This chapter presents and evaluates the alternatives to the originally proposed WSIP. In particular, it evaluates alternative water supply strategies that could meet most of the basic objectives of the WSIP.

- **Appendix E (Volume 5 of the PEIR):** This appendix supplements the information contained in Chapter 7 of the Draft PEIR on growth inducement impacts.

Text from the Final PEIR on the WSIP

In response to comments on the Draft PEIR, the SFPUC proposed several changes to the WSIP. These changes are detailed in the Final PEIR along with the environmental effects of the revised program. Therefore, this appendix also contains the following text from the Final PEIR on the WSIP:

- **Sections 13.2, 13.3, and 13.4 (Chapter 13, Volume 7a of the PEIR):** These sections describe changes in the WSIP that have been proposed by the SFPUC since publication of the Draft PEIR. The SFPUC has proposed revisions to the WSIP in three areas, either in response to comments received on the Draft PEIR or as part of its ongoing system operations and planning. These revisions include: (1) changes in the project descriptions of two WSIP facility improvement projects (both of which help reduce impacts associated with the projects as originally proposed) which affect overall system operations; (2) updated water system assumptions and corresponding updates in the system modeling and results; and (3) development of the Phased WSIP Variant, a "hybrid" program that is a combination of the proposed program and one of the alternatives analyzed in the Draft PEIR. The environmental impacts of the revised WSIP are also described.

Master responses provide comprehensive discussions to respond to select sets of issues that received multiple comments. The following master responses are included in this appendix to clarify the description of the WSIP and its impacts:

- **14.3 – Master Response on Proposed Dry-Year Water Transfer (Chapter 14, Volume 7a of the PEIR):** This master response explains the dry-year transfer component of the adopted WSIP.

- **14.5 – Master Response on Water Resources Modeling and Appendix O (Chapter 14, Volume 7a of the PEIR):** This master response addresses questions about the water resources model used for the impact analysis of

WSIP. It references "Appendix O," which is also included as part of this appendix.

- **14.9 – Master Response on Alameda Creek Fishery Issues (Chapter 14, Volume 7a of the PEIR):** This master response addresses comments on the adequacy of the impact analysis and mitigations with respect to the WSIP's effects on the steelhead fishery in Alameda Creek. It describes in detail the changes that were incorporated into two WSIP facility improvement projects: the Calaveras Dam Replacement Project and the Alameda Creek Fishery Enhancement Project.

- **14.10 – Master Response on Modified WSIP Alternative (Chapter 14, Volume 7a of the PEIR):** This master response addresses the issues commenters raised on the Modified WSIP Alternative, which was identified in the Draft PEIR as the environmentally superior alternative.

- **14.11 – Master Response on Climate Change (Chapter 14, Volume 7a of the PEIR):** This master response addresses issues raised by commenters concerning the impacts of the WSIP on climate change and global warming.

Chapters 5, 7, and 9 of the Draft PEIR on the WSIP are included in this appendix as described above. Several changes were made to these chapters in the Final PEIR. This section details these changes.

- **16 – Staff-initiated Text Changes for Chapters 5, 7, and 9 (Volume 7b of the PEIR):** This section contains text changes to the Draft PEIR that resulted from: (1) changes made in response to comments received on the Draft PEIR; (2) changes that reflect the WSIP revisions; or (3) changes to correct errors or to clarify information presented in the Draft PEIR. Where a response to a comment includes a change to the text of the Draft PEIR, the text changes are shown in underline for additions and ~~strikethrough~~ for deletions.

The Draft and Final PEIR on the WSIP may be reviewed in its entirety at the offices of the San Francisco Planning Department, 1650 Mission Street, Suite 400, San Francisco, CA 94103.

1.0 Project Overview

1.1 Project Background and Description

The City and County of San Francisco, through the San Francisco Public Utilities Commission (SFPUC), owns and operates a regional water system that extends from the Sierra Nevada to San Francisco and serves people in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne Counties. The regional water system consists of a network of facilities covering a geographic range of about 167 miles. Two existing components of the SFPUC water system are the Tesla Portal Hypochlorite Station, located at the Tesla Portal site, and the Thomas Shaft Chlorination Facility, located at the Thomas Shaft site. Both of these facilities are located in unincorporated portions of San Joaquin County.

The SFPUC is proposing to construct and operate three new facilities and associated supporting facilities and infrastructure, two at the Tesla Portal site, and one at the Thomas Shaft site. These improvements comprise the proposed San Joaquin Regional Water Quality Improvement Project (SJRWQIP):

- At the Tesla Portal site, the Tesla Portal Disinfection Station would replace the existing Tesla Portal Hypochlorite Station, which disinfects water to make it potable for public consumption, and construct and operate a new 10,000-square-foot building containing disinfection and related equipment, and install supporting facilities and infrastructure. The purpose of this effort is to have a chlorination facility that would fulfill current seismic, safety/fire, and building code standards, which the existing facility does not meet. The new chlorination facility would also improve current water quality management capabilities.

- The Advanced Disinfection Facility (ADF) at Tesla Portal would consist of a new 20,000-square-foot facility that would pass water by a series of ultraviolet (UV) light arrays. The purpose of this effort is to help SFPUC meet U.S. Environmental Protection Agency (USEPA) requirements for *Cryptosporidium* reduction in drinking water, as required under USEPA's Long Term-2 Enhanced Surface Water Treatment Rule (LT2ESWTR). *Cryptosporidium* is a parasite commonly found in lakes and rivers, which has caused several large waterborne disease outbreaks of gastrointestinal illness in other parts of the country.

- At Thomas Shaft, the Lawrence Livermore National Laboratory (LLNL) Supply Improvements would upgrade water treatment facilities. The purpose of this effort is to meet USEPA requirements under the Surface Water Treatment Rule (SWTR) for the inactivation of *Giardia*, as well as assist in meeting LT2ESWTR *Cryptosporidium* requirements. Like *Cryptosporidium*, *Giardia* is a parasite that can contaminate drinking water and cause gastrointestinal illnesses. This upgrade would enable the facility to supply potable water to a reservoir owned by LLNL at their facility serving LLNL Site 300, a 7,000-acre restricted-access parcel about 15 miles southeast of the main LLNL facility and about 1.5 miles north of the Thomas Shaft site, and thereby fulfill a contractual agreement with LLNL that specifies drinking water quantities to be delivered to that site. At the present time,

SFPUC cannot fulfill this agreement because the water at Thomas Shaft does not meet SWTR standards for *Giardia* inactivation.

Construction of the Tesla Portal Disinfection Station and ADF is anticipated to start in July 2009, and last for approximately 18 months to two years. Construction of the LLNL Supply Improvements is anticipated to start May 2010, and last for approximately one year.

The SJRWQIP, along with several other projects, are components of the SFPUC's regional Water System Improvement Program (WSIP). Aging facilities within the system are currently in need of major repair, rehabilitation, upgrade, and/or replacement. In February 2005, the SFPUC developed the WSIP (see www.sfwater.org). The basic goals of the WSIP are to increase the reliability of the regional water system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area through the year 2030. The implementation of the SJRWQIP would contribute to meeting the overall WSIP goals and objectives.

1.2 Environmental Review

The San Francisco Planning Department is the lead agency implementing environmental review under the California Environmental Quality Act (CEQA) for the proposed project. CEQA requires that the decision-making body and the public be informed about the potentially significant adverse environmental effects of a project, and identify ways to avoid or reduce those effects prior to project approval. The Planning Department's Major Environmental Analysis Section (MEA) determined that an Environmental Impact Report (EIR) is the appropriate level of environmental review for this proposed project. MEA will direct preparation of the EIR.

As part of the EIR process, the Planning Department held a public scoping meeting on June 6, 2007, to allow interested parties an opportunity to express their concerns about the proposed project's potential environmental impacts and to comment on the scope and content of the environmental review.

Following consideration of the public comments received during the scoping process, the Planning Department will prepare a Draft EIR on the project. The Draft EIR will include a description of the existing environmental conditions on and around the proposed project sites, and will identify significant impacts on the physical environment that could be caused by construction or operation of the project. The issues raised during the public scoping process will help to identify potentially significant impacts that should be studied and project alternatives that should be discussed in the EIR.

2.0 Public Scoping and Outreach Activities

The purpose of scoping is to provide the CEQA lead agency the opportunity to consult directly with interested public agencies, the public, and organizations and other interested parties on matters related to environmental effects associated with a proposed project. The scoping process helps identify actions, alternatives, and mitigation measures that should be considered in the EIR. It assists with the coordination of regulatory agencies, local agencies and other stakeholders who may have different views and concerns regarding environmental issues. Scoping activities can also serve as a means to engage a community, resolve issues early in the EIR process, and foster public participation.

2.1 Public Notification

On May 17, 2007, the San Francisco Planning Department issued a Notice of Preparation (NOP) of an Environmental Impact Report and Notice of a Public Scoping Meeting for the proposed project. A copy of the NOP is provided in Appendix A. The public comment period was held from May 17, 2007 to June 18, 2007. Public notice was provided as follows.

2.1.1 NOP and Scoping Meeting Notice Mailing

Approximately 750 copies of the NOP and Notice of Public Scoping Meeting were mailed on May 17, 2007 via certified mail to responsible agencies and by U.S. mail to all others on the mailing list. The mailing list included the following project stakeholder groups:

- Elected officials
- Public agencies
- Interest groups (environmental, business, general, civic)
- Water utilities and special districts
- Informational repositories (State Clearinghouse, libraries)
- Media outlets
- Property owners
- Local residents
- Other interested parties

The SFPUC mailed out approximately 600 postcards on May 24, 2007 to members of the public included in the mailing list announcing the scoping meeting.

2.1.2 Legal Notice

A legal notice was published in the Tracy Press and the San Francisco Chronicle on May 19, 2007. Copies of the legal notice are provided in Appendix B.

2.1.3 Project Website Information

The NOP and other information related to the proposed project were posted on the San Francisco Planning Department website http://www.sfgov.org/site/planning/mea.

The NOP information was also posted at the SFPUC website http://www.sfwater.org under "Water System Improvement Program," then "San Joaquin Region."

2.1.4 Copies of the NOP

A copy of the NOP was and is available to anyone upon request from the San Francisco Planning Department's Major Environmental Analysis Section office at 1650 Mission Street, Suite 400, or by calling (415) 575-9028. The NOP is also available online at the web address given above.

2.2 Scoping Meeting Overview

The San Francisco Planning Department's Major Environmental Analysis Section sponsored a public scoping meeting to solicit public input regarding project issues of concern to the community, and identify potential environmental effects and potential alternatives to be considered in the environmental review process. The meeting was held on June 6, 2007, at the Tracy Golf and Country Club, 35200 South Chrisman Road, in Tracy, California. The materials presented at the meeting are provided in Appendix C.

Fifteen people unrelated to the project staff attended the meeting and signed the sign-sheet (Appendix C): twelve members of the public (including one employee of the Tracy Golf and Country Club), and three employees of Lawrence Livermore National Laboratory.

Proceedings of the meeting were provided by a court reporter in the form of a written transcript. In addition, staff took summary notes of issues raised.

2.3 Scoping Meeting Presentations

The scoping meeting format consisted of an overview of the CEQA process by Paul Maltzer, the Environmental Review Officer of the San Francisco Planning Department's Major Environmental Analysis Section, followed by a description of the proposed project by Bijan Ahmadzadeh, the SFPUC Project Manager. A copy of the presentation used at the meeting is presented in Appendix C. Mr. Maltzer explained that the San Francisco Planning Department is the lead agency implementing CEQA for SFPUC projects. Mr. Maltzer summarized the CEQA process and the purpose of public scoping. He explained that the project sponsor and applicant, the San Francisco Public Utilities Commission, must consider the information in the EIR before making a decision to approve, modify or disapprove the project. Mr. Ahmadzadeh described the project in detail.

The EIR schedule and upcoming milestones were reviewed:

- Public Review of the Draft EIR: 2008
- Release of the Final EIR: 2008
- Certification of the Final EIR: 2008

Once the EIR is finalized, it will be considered for certification by the San Francisco Planning Commission. After certification, the SFPUC will evaluate the proposed project in light of the information in the EIR prior to taking any action on the project.

3.0 Summary of Scoping Comments

This section presents a summary of the comments received in verbal and written testimony provided at the June 6, 2007 public scoping meeting, and in subsequent letters received in response to the NOP. Approximately 15 people not affiliated with the project attended the scoping meeting, four of whom made verbal comments, and two of whom made written comments. During the public comment period, the San Francisco Planning Department received written comments in the form of four letters. Two additional letters were received after that period. The transcript of the public scoping meeting is presented in Appendix D. Written comments from the scoping meeting and comment letters are presented in Appendix E. Persons submitting oral and written comments are listed in Table 1. Table 2 provides a matrix of the types of concerns raised in each oral comment, comment card, or letter, showing the commenter's name and organization, if any. A summary or paraphrase of comments, organized by resource area topic, follows Table 2.

TABLE 1
NOP AND SCOPING MEETING COMMENTERS

Federal	• Lawrence Livermore National Laboratory - Keith Graham, Deputy Manager, Site 300 (comment card)
State	• California Department of Transportation – Tom Dumas, Office of Intermodal Planning (letter) • California Regional Water Quality Control Board, Central Valley Region (CVRWQCB) – Greg Vaughn, Senior Engineer, Stormwater and Water Quality Certification Unit (letter)
Regional	• Bay Area Water Supply & Conservation Agency (BAWSCA) – Nicole M. Sandkulla, Senior Water Resources Engineer (letter) • Modesto Irrigation District - Celia Aceves, Risk and Property Analyst (letter) • San Joaquin Valley Air Pollution Control District (SJVAPCD) - David Warner, Director of Permits Services; Arnaud Marjollet, Permit Services Manager (letter)
Public	• Linda Biscocho (oral comment) • Brian Jackman (oral comment) • Charles Tapia (oral comment) • Mark Wihl (oral comment) • Cletus Woo (comment card) • Tuolumne Band of Mi-Wuk Indians - Stanley Robert Cox, Cultural Resources Director (letter)

1. These agency letters stated that they had no comments on the NOP.

3.1 Summary of Comments, Organized by Concern

The following paragraphs summarize or paraphrase the public comments received on the Notice of Preparation. The letters received from the California Department of Transportation and the Modesto Irrigation District stated that neither agency had comments on the scope of issues to be addressed in the EIR.

Aesthetics

Questions about the overall appearance of new facilities at Tesla Portal. Will they be taller, wider, brightly painted, or otherwise create visual impacts? Will the facilities be landscaped? (#3 - Tapia at meeting, June 6, 2007)

Air Quality

Questions about chlorine at the Tesla Portal site. Will chlorine be dissipated in the air, and will it affect the air we breathe? (#1 - Biscocho at meeting, June 6, 2007)

Concern about the possible spill of chlorine into the air at the Tesla Portal site. (#3 - Tapia at meeting, June 6, 2007)

EIR should address construction dust impacts on Chrisman residents near the Tesla Portal site. (#4 - Biscocho at meeting, June 6, 2007)

EIR should address dust abatement. (#6 - Woo, comment card)

The project would contribute to the overall decline in air quality due to construction activities in preparation of the site, and ongoing traffic and other operational emissions. The SJVAPCD recommends that the air quality section of the EIR have four main components:

- Description of the regulatory environment and existing air quality conditions impacting the area [information sources are listed];

- Estimates of existing emissions and projected pollutant emissions related to the increase in project source emissions and vehicle use, along with an analysis of the effects of these increases. The analysis should include ozone precursors, toxic air pollutants, carbon monoxide hotspot analysis, and odor analysis;

- Identification and discussion of all existing District regulations that apply to the project [applicable SJVAPCD Rules are listed]; and

- Identification and discussion of all feasible measures that will reduce air quality impacts generated by the project. (#11 - SJVAPCD, letter, June 19, 2007)

Biological Resources

The wetland at Tesla Portal should be delineated to determine whether it is part of waters of the U.S. or waters of the State, with associated regulatory requirements (#9 - CVRWQCB, May 25, 2007)

Cumulative and indirect wetland impacts must be prevented. (#9 - CVRWQCB, May 25, 2007)

Coordination between WSIP and SJRWQIP EIRs

Information developed in the WSIP PEIR that is used in the project EIR should be appropriately referenced. (#7 - BAWSCA, letter, June 15, 2007)

Cultural Resources

The project has the potential to affect cultural resources, and a qualified firm should conduct a cultural resources survey. (#12 - Tuolumne Band of Mi-Wuk Indians letter, July 5, 2007)

Cumulative Impacts

The cumulative impacts discussion in the project EIR must be consistent with the WSIP PEIR. (#7 - BAWSCA, letter, June 15, 2007)

Energy

The project description should note that electrical consumption will increase with operation of the UV system, and the EIR should examine whether on- or off-site electrical upgrades would therefore be required. (#7 - BAWSCA, letter, June 15, 2007)

Growth

The growth-inducement discussion in the project EIR must be consistent with the WSIP PEIR. (#7 - BAWSCA, letter, June 15, 2007)

Hazardous Materials

Concern about the use of chlorine at the Tesla Portal site. (#1 - Biscocho at meeting, June 6, 2007)

Concern about a possible spill of chlorine at the Tesla Portal site. (#3 - Tapia at meeting, June 6, 2007)

Concern about evacuation drills and warning devices at the Tesla Portal site. Resident has never heard any evacuation drills or sirens at Tesla Portal in the 20 years he has lived in the area. Have there been any in response to a problem? Should there be any, as practice? (#4 - Wihl at meeting, June 6, 2007)

Questions about hazards. What are the hazards to the whole population and how can those hazards be mitigated in the case of a problem? (#4 - Wihl at meeting, June 6, 2007)

EIR should address asbestos abatement. (#6 - Woo, comment card)

EIR should address debris abatement. (#6 - Woo, comment card)

EIR should discuss whether there is soil and/or groundwater contamination at the sites. A preconstruction site investigation may be necessary, to evaluate whether contamination is present, and any contamination found should be reported to responsible agencies and remediated. (#9 - CVRWQCB, May 25, 2007)

Hydrology and Water Quality

EIR should evaluate depth to groundwater, whether it is expected to be encountered, how dewatering will be accomplished, and whether the groundwater is contaminated. Recommendations for handling groundwater are provided, including use of Best Management Practices. (#9 - CVRWQCB, May 25, 2007)

Construction activities will require National Pollutant Discharge Elimination System compliance. (#9 - CVRWQCB, May 25, 2007)

The project could increase the amount of impervious surfaces and result in an increase in the amount of stormwater runoff. The development and implementation of a Storm Water Management Plan and incorporation of Best Management Practices is recommended. (#9 - CVRWQCB, May 25, 2007)

Noise

EIR should address demolition/construction noise abatement. (#6 - Woo, comment card)

Will the facility mean more traffic down Vernalis, because I hear those trucks go down this street all the time. (#3 - Tapia at meeting, June 6, 2007)

Project Description

Questions asking whether any of the pipelines will be replaced and whether the project would take place only at the two sites [Tesla Portal and Thomas Shaft]. (#2 - Jackman at meeting, June 6, 2007)

Question about impacts to residents as a property owner. (#1 - Biscocho at meeting, June 6, 2007)

LLNL manager supports the expeditious progress of the LLNL Supply Improvements in meeting the City and County of San Francisco's obligation to deliver high-quality water to LLNL Site 300. (#5 - Graham, comment card)

Better description is needed of Cryptosporidium and Giardia, and their regulatory significance. (#7 - BAWSCA, letter, June 15, 2007)

Description of the LLNL Supply Improvements should clarify that Giardia inactivation is needed to comply with Surface Water Treatment Rule Standards, and reducing Cryptosporidium is necessary to comply with Long Term-2 Enhanced Surface Water Treatment Rule standards. (#7 - BAWSCA, letter, June 15, 2007)

Project description should include the size of the proposed control building, adjacent to the proposed ADF. (#7 - BAWSCA, letter, June 15, 2007)

Objective of the ADF should emphasize that the project is necessary to comply with more stringent federal and state drinking water regulations, and that to not build this project would lead to violation of Long Term-2 Enhanced Surface Water Treatment Rule standards. (#7 - BAWSCA, letter, June 15, 2007)

Traffic

EIR should address traffic impacts. (#4 - Biscocho at meeting, June 6, 2007)

Will the facility provide more water, therefore requiring more chlorine, and increasing the number of truck trips on Vernalis Road? (#3 - Tapia at meeting, June 6, 2007)

EIR should address potential Vernalis Road traffic increases, and road closures/blockages/detours. (#6 - Woo, comment card)

Water Supply

Can the owners of the properties through which the SFPUC water passes have access to that water? (#1 - Biscocho at meeting, June 6, 2007)

E-mail:	Jamie.Dean@sfgov.org	**Facsimile:** (415) 558-6409
Project Title:	San Joaquin Regional Water Quality Improvement Project	
Project Sponsor:	San Francisco Public Utilities Commission 1145 Market Street, Suite 401, San Francisco, CA 94103	
Contact Person:	Robin Breuer	**Telephone:** (415) 551-2915
E-mail:	RBreuer@sfwater.org	**Facsimile:** (415) 934-5750
Project Location:	Tesla Portal: 9000 West Vernalis Road, unincorporated San Joaquin County, California Thomas Shaft: Thomas Shaft Road (no address), unincorporated San Joaquin County, California	
Assessor's Block and Lot:	Tesla Portal: 253-160-02 Thomas Shaft: 251-330-10, 251-170-03	
Counties:	San Joaquin	

Project Description: The City and County of San Francisco, through the San Francisco Public Utilities Commission (SFPUC), owns and operates a regional water system that extends from the Sierra Nevada mountain range to San Francisco and serves people in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne Counties. The system consists of a complex network of facilities covering a geographic range of about 167 miles. Two components of the SFPUC water system are the Tesla Portal Hypochlorite Station, located at the Tesla Portal site, and the Thomas Shaft facility, both located in unincorporated portions of San Joaquin County.

The San Joaquin Regional Water Quality Improvement Project is part of the Water System Improvement Program (WSIP).[1] The basic goals of the WSIP are to increase the reliability of the regional water system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area through the year 2030. The proposed project, which is the subject of this NOP, along with several other projects, are components of the SFPUC's WSIP, and the implementation of this project would contribute to meetings the overall WSIP goals and objectives.

The San Joaquin Regional Water Quality Improvement Project is proposed to improve the disinfection capabilities of the Tesla Portal site and the Thomas Shaft site. The Tesla Portal Disinfection Station would be located at the Tesla Portal site and includes closing the existing Tesla Portal Hypochlorite Station and the construction and operation of replacement facilities. Also at the Tesla Portal site, the project would include the construction and operation of a new Advanced Disinfection Facility that would pass water by a series of ultraviolet light arrays. At the Thomas Shaft site, the Lawrence Livermore National Laboratory Supply Improvements would upgrade water treatment facilities.

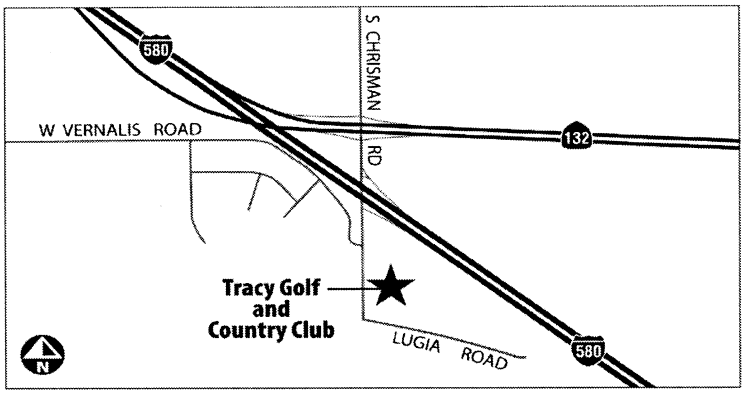
[1] The proposed project is listed as three separate projects in the WSIP NOP: the Tesla Portal Disinfection Facility, the Hetch Hetchy Advanced Disinfection, and the Lawrence Livermore Filtration. For the purposes of this EIR, these three projects are evaluated as one project given their geographic proximity, construction schedule, and the interrelated function of the two proposed facilities at the Tesla Portal site.

THIS PROJECT MAY HAVE A SIGNIFICANT EFFECT ON THE ENVIRONMENT. AN ENVIRONMENTAL IMPACT REPORT IS REQUIRED. This determination is based upon the criteria given in the following sections of the Guidelines of the State Secretary for Resources: 15064 (Determining Significant Effect) and 15065 (Mandatory Findings of Significance).

A **PUBLIC SCOPING MEETING** will be held, pursuant to the State of California Public Resources Code Section 21083.9 and California Environmental Quality Act (CEQA) Guidelines Section 15201, to receive oral comments concerning the scope of the Environmental Impact Report (EIR). The San Francisco Planning Department will hold a public scoping meeting at the following location, date, and time:

Tracy – June 6, 2007
Starting promptly at 6:30 p.m.

Tracy Golf and Country Club
35200 South Chrisman Road
Tracy, CA 95377



The purpose of this meeting is to receive oral comments to assist the San Francisco Planning Department in reviewing the scope and focus of the Project's environmental impact analysis and information to be contained in the EIR. The public will have the opportunity to comment and offer testimony for consideration. The San Francisco Planning Department will also accept written comments at the meeting or by mail, e-mail, or fax until the close of business on June 18, 2007. Written comments should be sent to the San Francisco Planning Department, Attn: Paul Maltzer, Environmental Review Officer, San Joaquin Regional Water Quality Improvement Projects EIR, 1650 Mission Street, Suite 400, San Francisco, CA, 94103-2479, by fax to (415) 558-6409, or sent by e-mail to Jamie.Dean@sfgov.org.

Documents relating to the Project are available for review, by appointment only, at the San Francisco Planning Department's Major Environmental Analysis office at 1650 Mission Street, Suite 400. Please call (415) 575-9028. Documents are also available online at:

RE: CASE NO. 2007.0427E – SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT
NOTICE OF PREPARATION OF AN ENVIRONMENTAL IMPACT REPORT AND NOTICE OF PUBLIC SCOPING MEETING

A Notice of Preparation (NOP) of an environmental impact report (EIR) pursuant to the California Environmental Quality Act (CEQA) and a Notice of Public Scoping Meeting for the above-referenced project, described below, has been issued by the San Francisco Planning Department. The NOP and Notice of Public Scoping Meeting is either attached or is available upon request from Jamie Dean, whom you may reach at (415) 575-9028, voice; (415) 558-6409, fax; Jamie.Dean@sfgov.org; or by mail at 1650 Mission Street, Suite 400, San Francisco, CA 94103-2479. The combined NOP/Notice of Public Scoping Meeting is also available online at http://www.sfgov.org/site/planning/mea and www.sfwater.org.

Project Description: The City and County of San Francisco, through the San Francisco Public Utilities Commission (SFPUC), owns and operates a regional water system that extends from the Sierra Nevada mountain range to San Francisco and serves people in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne Counties. The system consists of a network of facilities covering a geographic range of about 167 miles. Two components of the SFPUC water system are the Tesla Portal Hypochlorite Station, located at the Tesla Portal site, and the Thomas Shaft facility, both located in unincorporated portions of San Joaquin County.

SFPUC proposes the San Joaquin Regional Water Quality Improvement Project, which is part of the Water System Improvement Program (WSIP).[1] The basic goals of the WSIP are to increase the reliability of the regional water system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area through the year 2030. The proposed project, which is the subject of this NOP, along with several other projects, are components of the SFPUC's WSIP, and the implementation of this project would contribute to meeting the overall WSIP goals and objectives.

The San Joaquin Regional Water Quality Improvement Project is proposed to improve the disinfection capabilities of the Tesla Portal site and the Thomas Shaft site. The Tesla Portal Disinfection Station would be located at the Tesla Portal site and includes closing the existing Tesla Portal Hypochlorite Station and the construction and operation of replacement facilities. Also at the Tesla Portal site, the project would include the construction and operation of a new Advanced Disinfection Facility that would pass water by a series of ultraviolet light arrays. At the Thomas Shaft site, the Lawrence Livermore National Laboratory Supply Improvements would upgrade water treatment facilities.

[1] The proposed project is listed as three separate projects in the WSIP NOP: the Tesla Portal Disinfection Facility, the Hetch Hetchy Advanced Disinfection, and the Lawrence Livermore Filtration. For the purposes of this EIR, these three projects are evaluated as one project given their geographic proximity, construction schedule, and the interrelated function of the two proposed facilities at the Tesla Portal site.

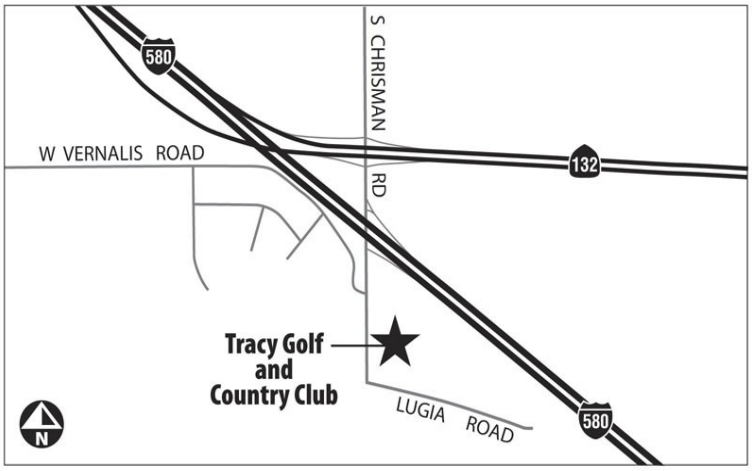
The San Francisco Planning Department's Major Environmental Analysis Division (MEA) is preparing an EIR for consideration by decision-makers prior to a final decision by the SFPUC regarding whether to approve and implement the project. The purpose of the EIR is to provide information about potentially significant adverse environmental effects of the proposed Project, to identify possible ways to minimize those potentially significant adverse effects, and to describe and evaluate feasible alternatives to the proposed Project. Preparation of an NOP or EIR does not indicate a decision by the City to approve or to disapprove the proposed Project. However, prior to making any such decision, the decision makers must review and consider the information contained in the EIR.

The San Francisco Planning Department will hold one **PUBLIC SCOPING MEETING** at the place, date, and time listed below. The purpose of this meeting is to receive oral comments to assist the San Francisco Planning Department in reviewing the scope and focus of the Project's environmental impact analysis and information to be contained in the EIR. Written comments will also be accepted at this meeting and until the close of business on June 18, 2007. Written comments should be sent to the San Francisco Planning Department, Attn: Paul Maltzer, Environmental Review Officer, San Joaquin Regional Water Quality Improvement Project EIR, 1650 Mission Street, Suite 400, San Francisco, CA 94103-2479, or provided via email to Jamie.Dean@sfgov.org, or by fax to (415) 558-6409.

Scoping Meeting

Tracy – June 6, 2007
Starting promptly at 6:30 p.m.

Tracy Golf and Country Club
35200 South Chrisman Road
Tracy, CA 95377



If you work for an agency that is a Responsible or Trustee Agency, we need to know the views of your agency as to the scope and content of the environmental information that is relevant to your agency's statutory responsibilities in connection with the proposed project. Your agency may need to use the EIR when considering a permit or other approval for this project. We will also need the name of the contact person for your agency. If you have questions concerning environmental review of the proposed project under CEQA, please contact Jamie Dean at (415) 575-9028.

San Joaquin Regional Water Quality Improvement Project

CASE NO. 2007.0427E

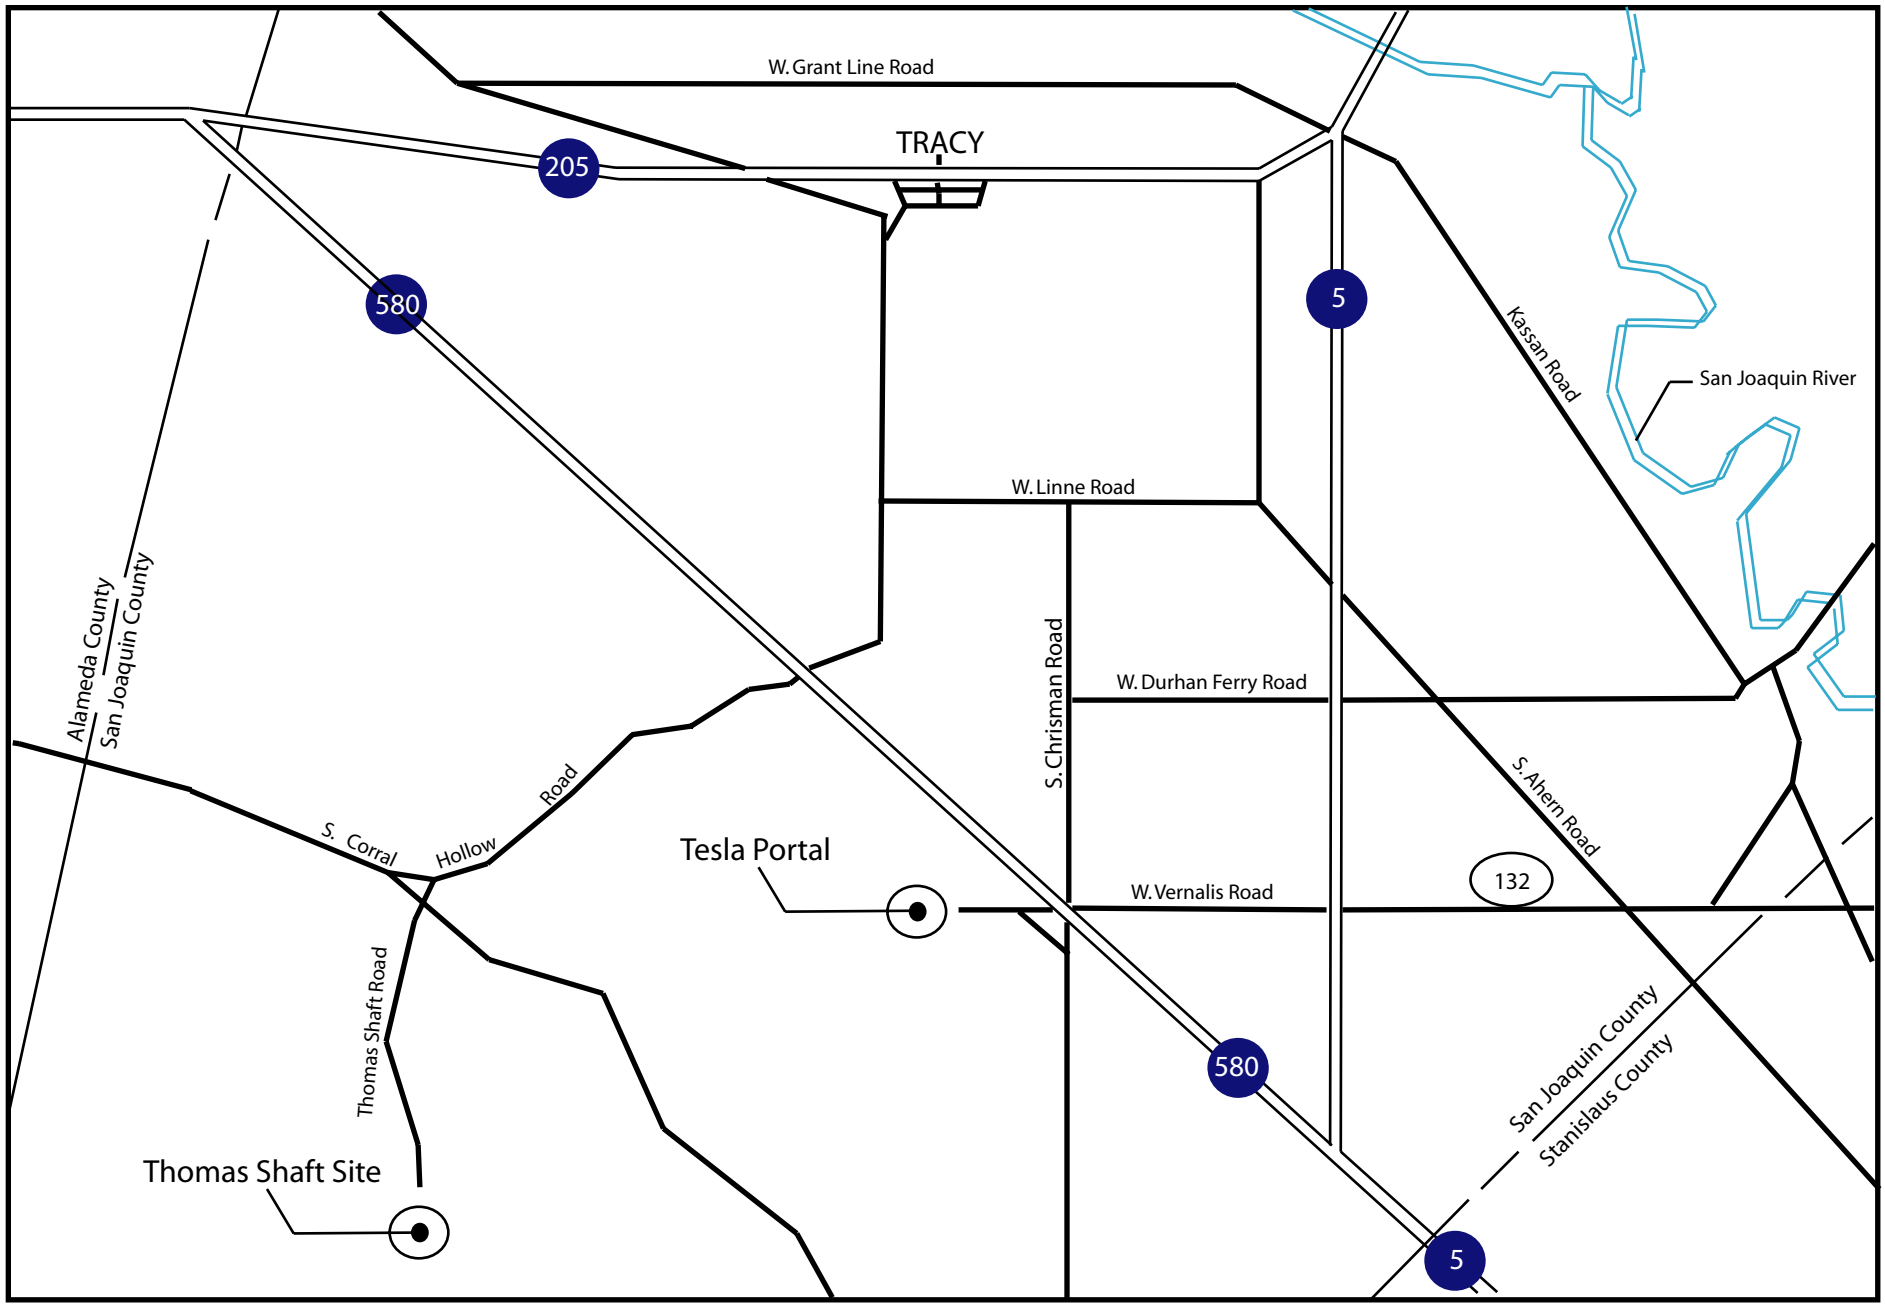
1.0 OVERVIEW AND BACKGROUND

The San Francisco Public Utilities Commission (SFPUC) is proposing to construct and operate three new facilities, two at the Tesla Portal site, and one at the Thomas Shaft site. (Figure 1, Vicinity Map). The three facilities comprise the proposed project, which is titled the *San Joaquin Regional Water Quality Improvement Project*. To meet California Environmental Quality Act (CEQA) requirements, the San Francisco Planning Department's Major Environmental Analysis (MEA) Division will prepare and distribute an Environmental Impact Report (EIR) describing and analyzing the environmental effects of the proposed project. This Notice of Preparation (NOP) describes the existing facilities at the proposed project site, proposed new facilities, and potential environmental effects of the proposed project.

1.1 San Francisco Water System, the Tesla Portal Hypochlorite Station, and the Thomas Shaft Facility

The City and County of San Francisco, through the SFPUC, owns and operates a regional water system that extends from the Sierra Nevada mountain range to San Francisco and serves people in San Francisco, San Mateo, Santa Clara, and Alameda Counties, and some residents in Tuolumne County, including the Town of Groveland. The regional water system consists of a network of facilities covering a geographic range of about 167 miles (Figure 2, SFPUC Regional Water System). Two existing components of the SFPUC water system are the Tesla Portal Hypochlorite Station, located at the Tesla Portal site, and the Thomas Shaft facility, located at the Thomas Shaft site. Both of these facilities are located in unincorporated portions of San Joaquin County.

Although the population within the SFPUC service area has steadily grown, repairs, maintenance, and upgrades have not kept pace with overall system needs to meet the increasing water purchase requests from SFPUC customers. Aging facilities within the system are currently in need of major repair, rehabilitation, upgrade, and/or replacement. In February 2005, the SFPUC developed a regional Water System Improvement Program (WSIP) (see www.sfwater.org). The basic goals of the WSIP are to increase the reliability of the regional water system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area through the year 2030. A programmatic EIR is currently being prepared by the San Francisco Planning Department to address the potential environmental impacts of the WSIP on a programmatic level and evaluate regional water supply alternatives. The proposed project, which is the subject of this NOP, along with several other projects, are

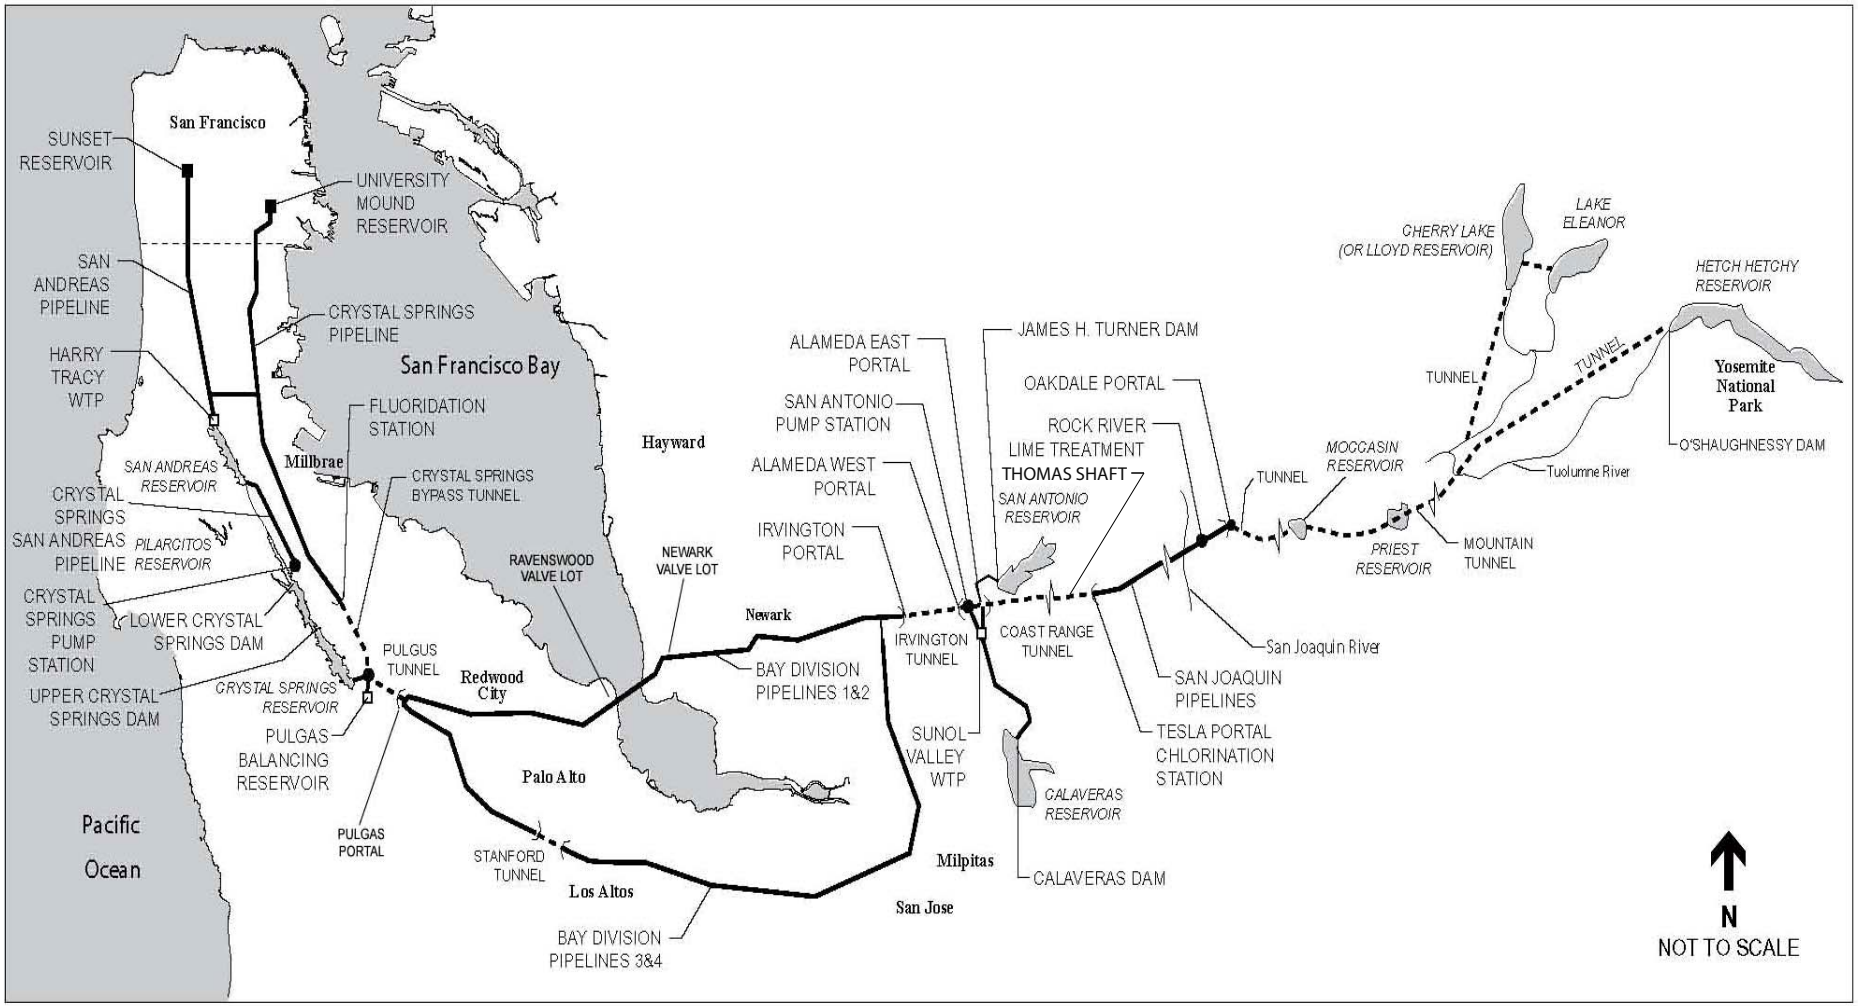


Not To Scale

SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT

Vicinity Map

Figure 1



SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT

SFPUC Regional Water System

Figure 2

components of the SFPUC's WSIP, and the implementation of this project would contribute to meeting the overall WSIP goals and objectives.[1]

1.2 Environmental Review Process

The MEA will prepare a project-specific EIR to evaluate the environmental effects of the San Joaquin Regional Water Quality Improvement Project proposed by the SFPUC. The EIR will be prepared in compliance with CEQA Guidelines Section 15161 and will address the project-specific construction and operational environmental impacts of the proposed project.

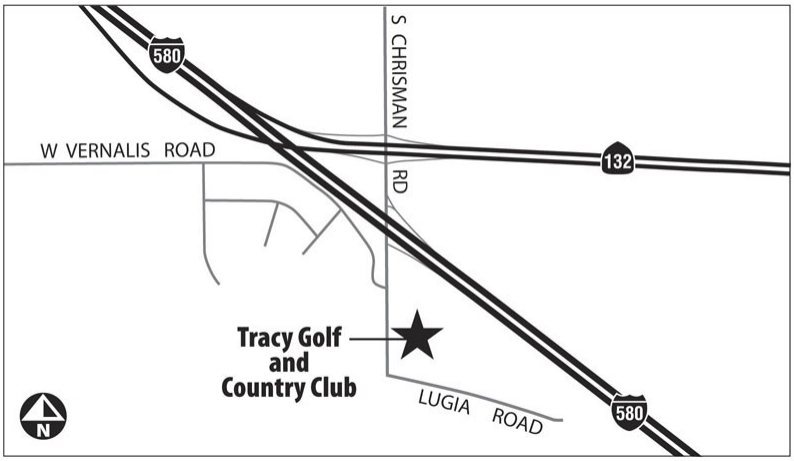
The first step in the environmental review process is the formal public scoping process. Following the public scoping meeting, a Draft EIR will be prepared and circulated for a 45-day public review period. Public comments on the Draft EIR will be accepted in writing during the review period or orally at a formal public hearing to be held by the San Francisco Planning Commission. MEA will then prepare written responses to comments on environmental issues raised during the public review period, and a Response to Comments document will be prepared. This document will be considered by the Planning Commission, along with the Draft EIR and any revisions to the draft based on the responses to comments, for certification as a Final EIR.

1.3 Public Scoping Meeting

MEA will hold one public scoping meeting at the following location, date, and time:

Tracy – June 6, 2007
Starting promptly at 6:30 p.m.

Tracy Golf and Country Club
35200 South Chrisman Road
Tracy, CA 95377



[1] The proposed project, which is the subject of this NOP, is listed as three separate projects in the WSIP NOP: the Tesla Portal Disinfection Facility, the Hetch Hetchy Advanced Disinfection, and the Lawrence Livermore Filtration. For the purposes of this EIR, these three projects are evaluated as one project given their geographic proximity, construction schedule, and the interrelated function of the two proposed facilities at the Tesla Portal site.

The purpose of this meeting is to assist MEA in determining the proposed scope and content of the EIR as summarized in Section 3.0 of this NOP. The public will have the opportunity to comment and offer testimony for consideration. MEA will also accept written comments at the meetings or by mail, e-mail, or fax until the close of business on June 18, 2007. Written comments should be sent to the San Francisco Planning Department, Attn: Paul Maltzer, 1650 Mission Street, Suite 400, San Francisco, CA 94103-2479, by fax to (415) 558-6409, or sent by e-mail to Jamie.Dean@sfgov.org.

1.4 Project Approvals

Following completion of the environmental review, the SFPUC will hold a public hearing to consider approval of the proposed project. Approvals will also be required from the Central Valley Regional Water Quality Control Board, and the San Joaquin Valley Unified Air Pollution Control District.

2.0 PROJECT DESCRIPTION

2.1 Existing Facilities and Project Components

2.1.1 Existing Facilities

Tesla Portal. The Tesla Portal site is located at 9000 West Vernalis Road, about 7.5 miles south of the city of Tracy, in unincorporated southwestern San Joaquin County. The site as a whole is about 52 acres; the proposed project would occur on a small portion (about five acres) of the site.

The Tesla Portal Hypochlorite Station, constructed in 1937, is located at the entrance to the Coast Range Tunnel and is the primary disinfection point for all waters emanating from the Hetch Hetchy Aqueduct. At the Tesla Portal Hypochlorite Station, sodium hypochlorite, a liquid form of chlorine and equivalent to chlorine bleach, is injected into the Coast Range Tunnel, utilizing two 13,000-gallon tanks outside the facility and four 4,000-gallon tanks inside the facility, to inactivate viruses and *Giardia*. No chlorine gas is released during the process. The existing Tesla Portal Hypochlorite Station handles a maximum flowrate of 290 million gallons per day (mgd) and an average flowrate of 220 mgd. It is operated continuously 24 hours per day as an unmanned facility, with routine maintenance of facility components. Facility operations are remotely monitored and controlled via the SFPUC's Supervisory Control and Data Acquisition (SCADA) System.

The primary structure at the site is the Tesla Portal structure, a 10.5-foot diameter steel manifold where three pipelines join and enter the Coast Range Tunnel. A steel overflow/surge shaft rises approximately 100 feet from a hillside near the Tesla Portal structure. The oldest buildings at the site are a wood-frame building housing the chlorination unit, a pump house, and a watershed keeper's cottage, all built in 1936.

Two valve houses were later added in 1949 and 1963. Three 20,000-gallon holding tanks are located on a hillside above the other buildings. Various minor upgrades and improvements have been added over the years, including an improved road and security gates in 2003.

Thomas Shaft Site. The Thomas Shaft site is located about 4.4 miles downstream from Tesla Portal, and about seven miles southwest of the city of Tracy in unincorporated southwestern San Joaquin County. The Thomas Shaft site as a whole is about 28 acres; the proposed project would occur on the developed portion of the site, which totals approximately one acre. Access to the developed portion of the site is via Thomas Shaft Road, a private road starting at Corral Hollow Road about 1.5 miles north of the site.

In the developed portion of the Thomas Shaft site, a tunnel and access shaft were constructed when the Hetch Hetchy Aqueduct was first installed in the area. The site also contains a backup chlorination facility, constructed in 1995 and modernized and upgraded in 2001, to chlorinate Hetch Hetchy water if adequate chlorination does not occur at the Tesla Portal Hypochlorite Station. The facility can be operated either onsite or remotely using the SCADA system. Components of the facility include a chemical receiving and storage facility, a chemical unloading area, and a control and power supply area. The chemical receiving and storage facility contains three 6,000-gallon hypochlorite tanks, several pumps, and associated piping and sensors. The facility also has water quality analyzers that sample water for quality control.

SFPUC and Lawrence Livermore National Laboratory (LLNL) have a contract, executed in 1960 and amended in 1987, under which SFPUC is to supply water to LLNL Site 300 after treatment at Thomas Shaft. To assist in water delivery, LLNL installed a ten-inch water line and pumps in 1995 across Thomas Shaft Road from the chlorination facility. However, because Thomas Shaft cannot meet the U.S. Environmental Protection Agency's (USEPA) Surface Water Treatment Rule (SWTR) standards for the inactivation of *Giardia*, SFPUC has not delivered water to Site 300 to date.[2]

2.1.2 Project Components

Tesla Portal Disinfection Station. The Tesla Portal Disinfection Station would be located at the Tesla Portal site. The proposed project includes replacement and upgrade of the existing disinfection facilities at the Tesla Portal Hypochlorite Station to meet current seismic, safety/fire, and building code standards. Sodium hypochlorite would be fed from a new Chemical Process Building and injected into the San Joaquin Pipelines. Although the location of the chlorination function at the site would move, the chlorine

[2] The current water supply for Site 300 comes from onsite wells serving a population of about 250 workers and visitors. The wells are owned by the Department of Energy/National Nuclear Security Administration, and operated by the contractor in charge of LLNL (currently the University of California).

injection process itself would be essentially unchanged. In addition, to lower the pH of the water, fluoride and sulfuric acid would be added.

The facility would continue to be remotely monitored and operated, although, as is true for the existing system, controls for manual operation would also be provided. Existing disinfection buildings on the site that would no longer be used would be maintained to prevent deterioration, and would not be occupied, although they might be used to store equipment.

Development associated with the new Advanced Disinfection Facility would include:

- Chemical Process Building. This new, approximately 10,000-square-foot building would be bermed into the adjacent hillside to help regulate building temperature. Contents would include the following:

  - Three 15,000-gallon sodium hypochlorite storage tanks

  - Two 10,000-gallon hydrofluosilicic acid (i.e., fluoride) storage tanks

  - Two 10,000-gallon sulfuric acid tanks

  - Sulfuric acid injection pH reduction system

  - Chemical spill containment system

  - Electrical room

  - Shop/storage room

  - Chemical feed equipment: metering pumps, transfer pumps, piping, and instrumentation (e.g., pressure gauges, flow meters, and tank level indicators)

- Office and Control Building. This new, approximately 2,400-square-foot building would contain offices, control room, laboratory, restrooms, lockers, shower, and a multipurpose room.

- Emergency back-up power supply

- Heating, ventilation, and air conditioning systems, installed inside the buildings

- Fire protection systems, using water sprinklers, dry chemical systems and/or fire hydrants; with the exception of the hydrants, installed inside the buildings

- Outdoor lighting.

Advanced Disinfection Facility (ADF). This facility would also be located at the Tesla Portal site. The new facility would allow the SFPUC to achieve the high level of disinfection required to reduce *Cryptosporidium* to levels mandated under Long Term-2 Enhanced Surface Water Treatment Rule (LT2ESWTR) by running Hetch Hetchy water past arrays of ultraviolet (UV) lamps. Facilities to be installed would include:

- UV Building. Contents of this new, approximately 20,000-square-foot building would include the following:

  - Twelve new UV reactors, each containing several UV lamp arrays and various sensors

  - Below-grade piping vaults

  - Two 3,000-gallon food-grade acid tanks (probably citric acid), for periodic cleaning of the UV lamps, attached to a UV lamp cleaning system

  - Diesel standby power generators and two aboveground diesel fuel tanks, probably 5,000 gallons each.

Other activities proposed at the Tesla Portal site that would benefit one or both of the above facilities, include:

- Road improvements. The following would be installed or constructed:

  - Paved approximately 0.5-mile circulation loop road in front of the Chemical Process Building connecting to the existing roadway

  - Chemical truck delivery area adjacent to the proposed Chemical Process Building

  - Paved parking areas on each side of the Office and Control Building, providing a total of three parking spaces

  - New asphalt surfacing of the existing access road

- Valves and valve vaults, to direct adequate flow as required

- Two emergency standby 750 kilowatt propane- or diesel-fueled generators

- Security improvements, including an eight-foot high fence surrounding the approximately five-acre area in which the new treatment facilities would be located (see below), and installing the following new features: controlled gate and entry system, closed circuit television monitoring system, and intrusion detection system.

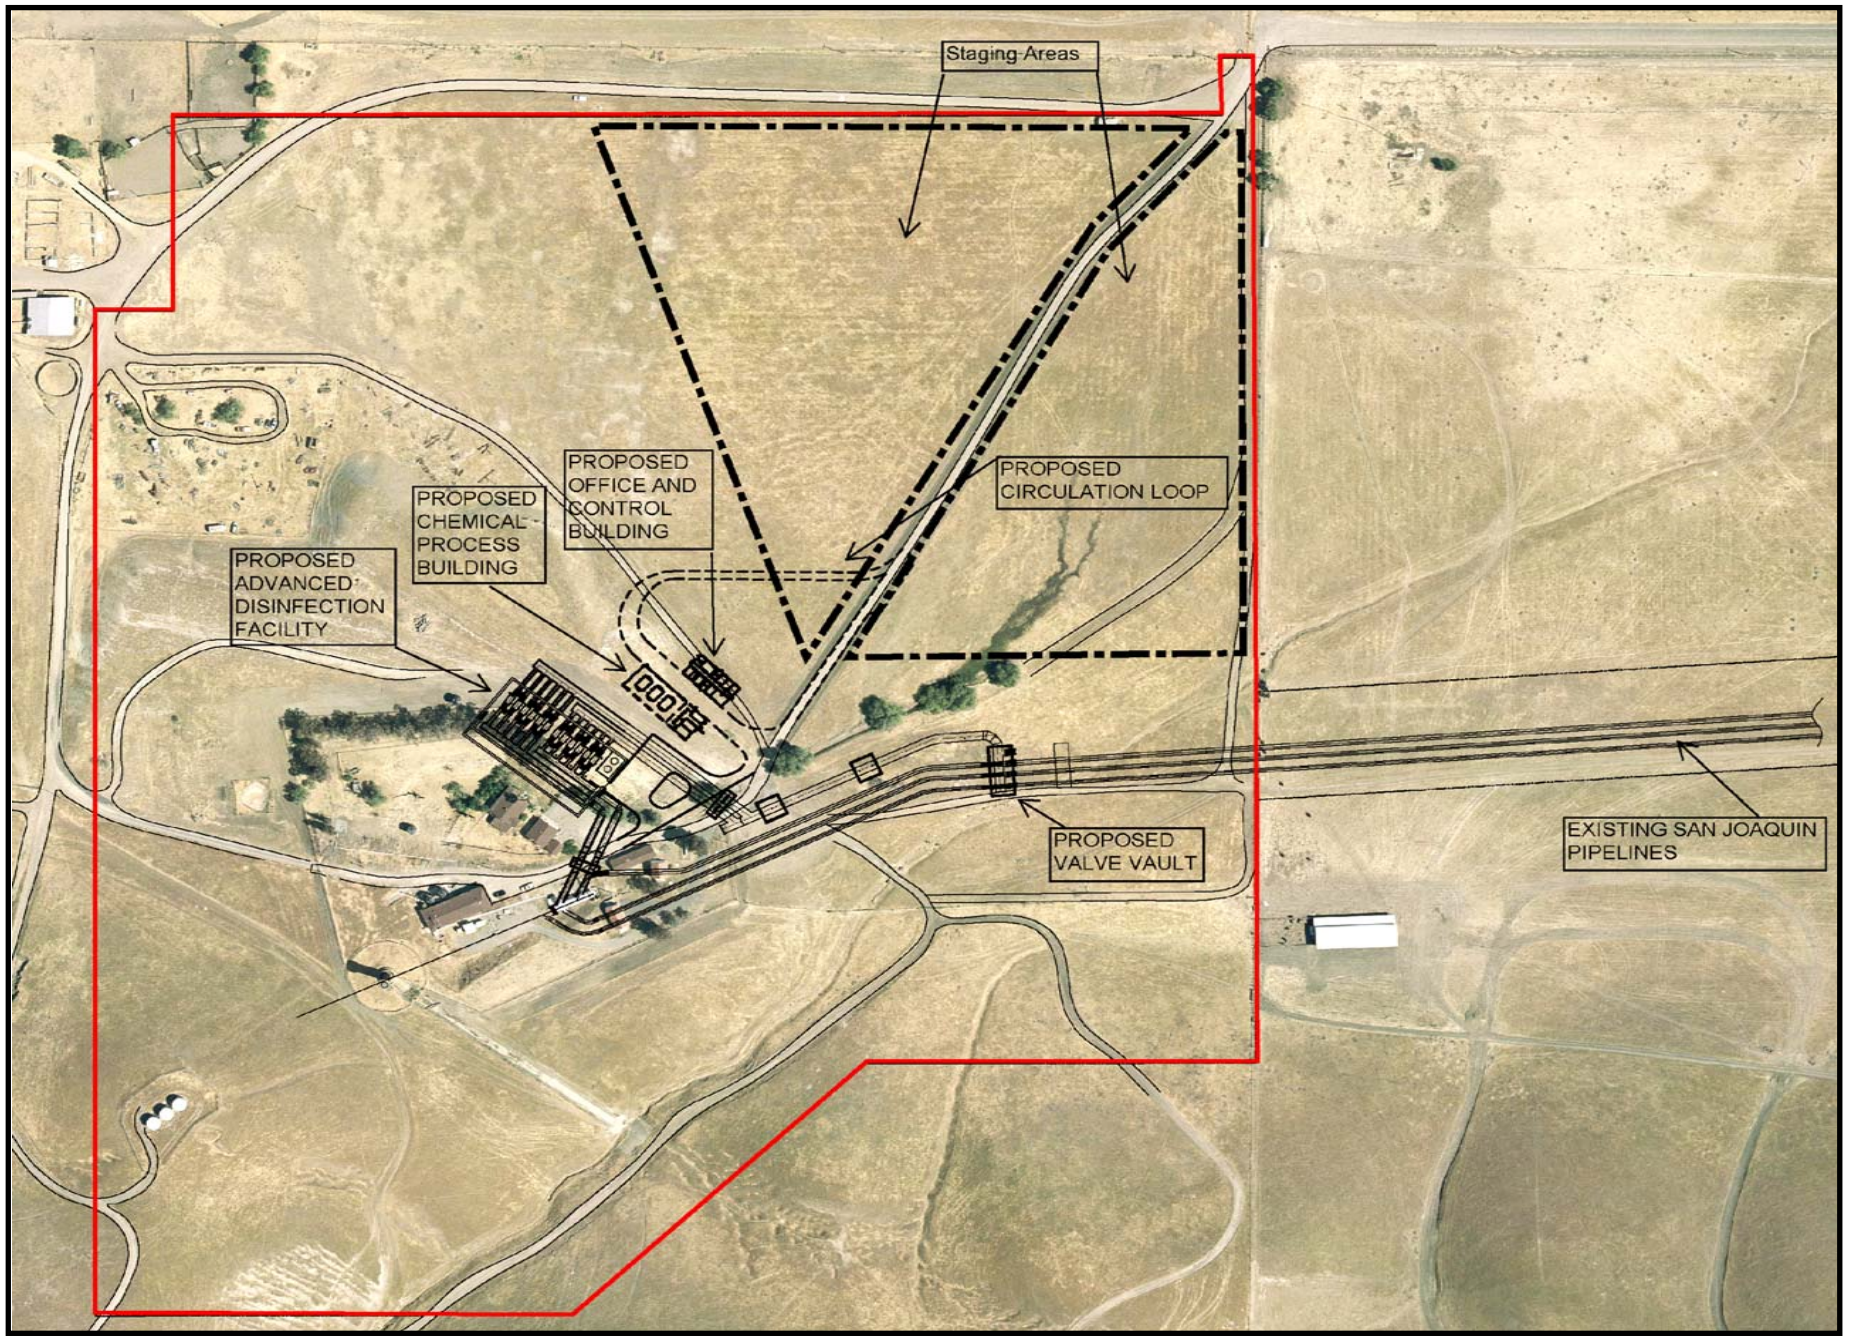
Refer to Figure 3 (Tesla Portal Site Plan) for the location of the proposed Tesla Portal Disinfection Station, ADF, and additional project features. The new facilities, including buildings and paved areas, would be constructed northeast of existing structures at Tesla Portal, on an approximately five-acre site that currently is undeveloped grassland. An additional approximately 12-acre undeveloped grassland area extending on both sides of the entrance road would be used for staging.

For both facilities at the Tesla Portal site, electricity consumption would increase and would require several electrical upgrades. Natural gas service would not be required for the new facilities.

Telephone service would be extended to new structures from existing connections to the Tesla Portal site. Drinking water would be obtained from the existing SFPUC system serving the site. To handle sewage and graywater, a new septic tank and leachfield would be installed to the north of the new facilities. Storm water would be caught and directed away from the new structures and released in a soakaway system that would be located near the leachfield.

Each of these facilities would require that existing vegetation in the vicinity be cleared and the sites graded. The existing disinfection function of Tesla Portal would not be interrupted as a result of the project.

LLNL Supply Improvements. SFPUC has a contractual agreement with LLNL to deliver drinking water to LLNL Site 300, under which the maximum rate of flow contracted will not exceed 0.8 mgd (556 gallons per minute). Presently, SFPUC cannot meet this agreement because water from Thomas Shaft does not meet SWTR standards for *Giardia* inactivation. To meet SWTR requirements, and assist in meeting LT2ESWTR requirements, the treatment facility at Thomas Shaft would be upgraded by installation of a UV disinfection system. (Figure 4, Lawrence Livermore Supply Improvements.) This would be installed in a new approximately 300-square-foot building at the site, and consist of two UV reactors, each containing several UV lamp arrays, as well as a power supply and control panel.



Project Boundary

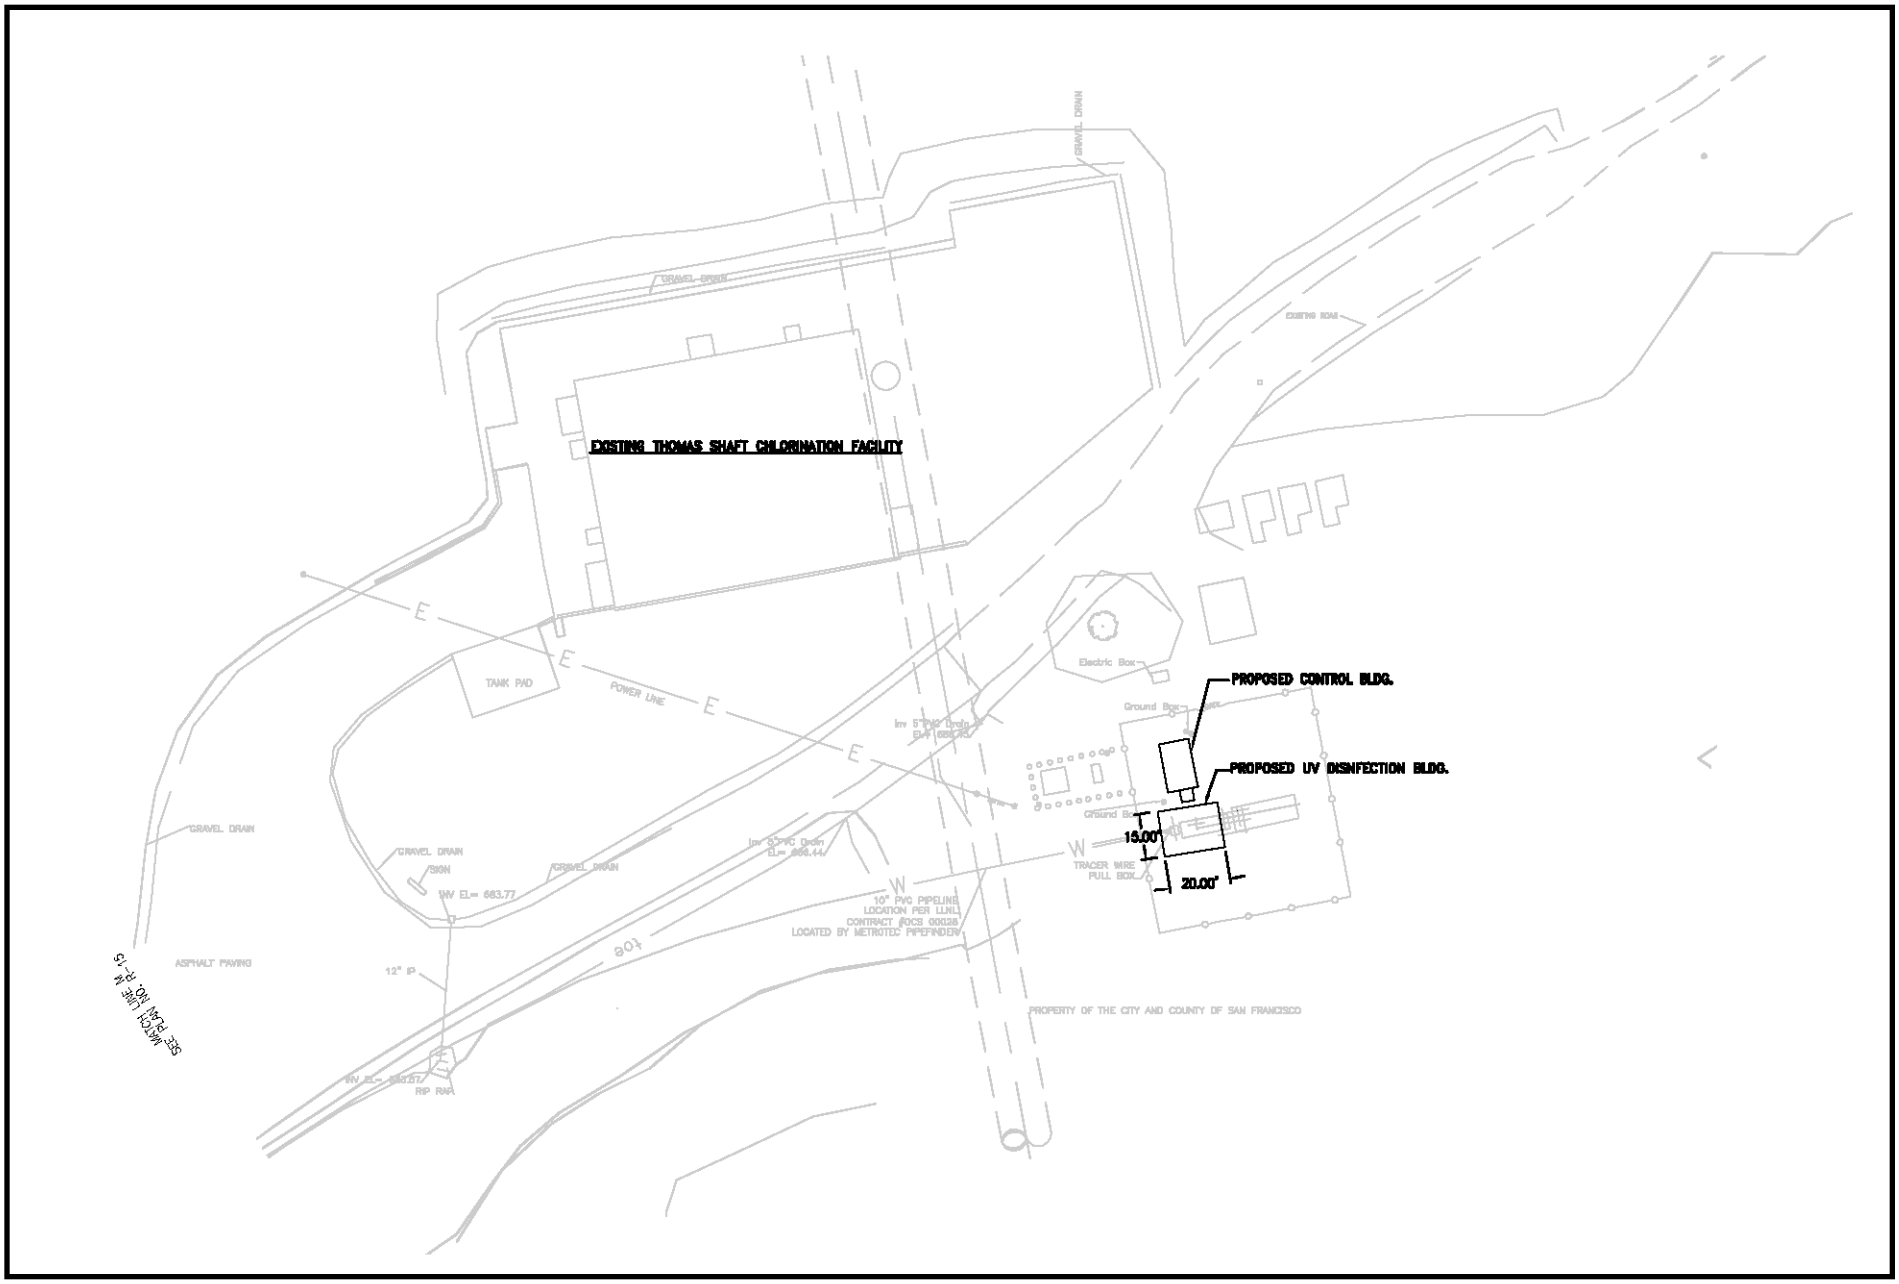
Limits of Staging Areas

Not To Scale

SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT

Tesla Portal Site Plan

Figure 3



Not To Scale

SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT

Lawrence Livermore Supply Improvements

Figure 4

The UV system likely would be installed partially on an existing graveled area across Thomas Shaft Road from the backup chlorination facility, and partially on grassland, which would be cleared and graded. Existing operations, which are minimal in any case, would not be interrupted as a result of the project. No new utility service from offsite sources would be required.

2.2 Project Goals and Objectives

The goals and objectives of the proposed project for each new project component are described below.

- Tesla Portal Disinfection Station. The objective of this facility is to have in place a chlorination facility at the Tesla Portal that would meet current seismic, safety/fire, and building code standards, which are not met by the existing facility. The new chlorination facility would also improve current water quality management capabilities.

- Advanced Disinfection Facility. The objective of this facility is to meet USEPA requirements for *Cryptosporidium* reduction in drinking water.

- LLNL Supply Improvements. The objective of this facility is to meet USEPA requirements for the inactivation of *Giardia*, assist in meeting USEPA *Cryptosporidium* requirements, and fulfill a contractual agreement between SFPUC and LLNL for supplying drinking water to LLNL Site 300.

2.3 Schedule

Tesla Portal Disinfection Station and Advanced Disinfection Facility. Construction of both facilities is anticipated to start in July 2009, and last for approximately 18 months to two years.

LLNL Supply Improvements. Construction is anticipated to start May 2010, and last for approximately one year.

Construction of the proposed project would be conducted on weekdays during daylight hours. No road closures are anticipated.

3.0 ENVIRONMENTAL ANALYSIS

3.1 Key Environmental Issues to be Addressed in the EIR

The EIR will address all environmental issue areas required under CEQA. The EIR will address both construction and operation activities and will propose mitigation measures for impacts considered to be

potentially significant adverse impacts. The following paragraphs describe the key environmental issues that the EIR will address.

Land Use, Agriculture and Recreation

The proposed project would not alter existing land uses and would not expand the boundaries of the Tesla Portal or Thomas Shaft sites, and it is anticipated that no significant land use impacts would result.

The proposed project would not reduce or otherwise affect agricultural land, and do not include construction of facilities that would result in additional population in the local area; thus, it is not anticipated to have any effects on agriculture and recreation. However, these topics also will be addressed in the EIR.

Employment, Population and Housing

A small number of permanent employees would be added at Tesla Portal as a result of the project. The construction activities would be short-term (anticipated maximum of two years), and construction workers are not anticipated to move permanently into the area as a result. While impacts of the project at both Tesla Portal and Thomas Shaft are anticipated to be less than significant, effects on employment, population, and housing will be addressed in the EIR.

Aesthetics

The installation of the new aboveground structures at the Tesla Portal site could result in visual impacts. Interstate 580, about one-half mile away, is a designated State Scenic Highway. The EIR will address the impacts of the proposed project on the aesthetic values of the proposed project area. Due to the remote location of the Thomas Shaft facility, the lack of any neighboring public roads or facilities, and the small scale of the proposed improvements, no aesthetic impacts are anticipated to occur from the LLNL Supply Improvements. However, the aesthetic impacts of the project will be addressed in the EIR.

Biological Resources

Construction of the proposed facilities could impact sensitive biological resources at both sites. The Tesla Portal site has a small wetland area which during site visits in fall 2006 was observed to have standing water and emergent vegetation. The water source for this area is runoff from sampling points at the existing Disinfection Station. Construction of the proposed facilities could affect this wetland if they were to, for example, cut off its source of water, discharge sediments or fill material to it, or remove wetland vegetation. Habitat suitable for several listed species, including San Joaquin kit fox and western burrowing owl, is present at Tesla Portal. No wetlands, creeks, or streams are present in the immediate vicinity of the Thomas Shaft site. However, several species, including San Joaquin kit fox and western

burrowing owl, could be adversely affected by the LLNL Supply Improvements. The EIR will address potential impacts on sensitive biological resources.

Cultural Resources

Historic resources are present at and/or are in the vicinity of both the Tesla Portal and Thomas Shaft sites. For example, as described earlier, several of the buildings at Tesla Portal are over 50 years old. Structures adjacent to the Thomas Shaft site were part of the original Hetch Hetchy Water System, which was completed in 1934. No prehistoric sites have been identified at either location; however, safeguards would be required if excavations uncovered archeological or paleontological resources. Although the project is not anticipated to adversely affect cultural resources (e.g., no structures at either site would be demolished), impacts on these resources will be addressed in the EIR.

Geology and Soils

A potentially active fault, the San Joaquin Fault, may be at or near the Tesla Portal site. No active faults have been mapped with the boundaries of the Thomas Shaft site. The project sites also may be subject to slope instability. Geologic hazards will be evaluated in the EIR.

Hydrology, Groundwater and Water Quality

Construction of the proposed project could affect surface water and groundwater resources (e.g., through erosion of soil resulting from construction activities, and from the creation of permanent impervious surfaces, affecting stormwater runoff). The EIR will evaluate the potential effects of erosion and any direct discharges into waterways during construction.

Hazards and Hazardous Materials

Neither project location is listed on state-maintained listings of sites with contaminated soil or groundwater, or that have hosted leaking underground storage tanks. However, hazardous materials have been used at both sites, and contaminated soils or contaminated groundwater might be encountered during construction. Additional hazardous materials would be stored and used in the future at the sites as a result of the proposed project. Hazardous building materials (e.g., asbestos) are not anticipated to be encountered during the project, as no building demolition would take place and project activities would not create situations where such materials would be encountered. However, the EIR will address potential environmental impacts from hazardous building materials and hazardous chemicals. In addition, both sites are in rural vegetated areas, and potential wildland fire impacts will be addressed.

Transportation, Circulation and Parking

Construction of the facilities would generate truck deliveries and worker trips, and operation of the facilities would generate new commuter trips and truck traffic (e.g., deliveries of disinfection chemicals) above baseline levels. No significant impacts upon circulation and parking are anticipated: parking of construction equipment and commuting personnel would take place entirely within SFPUC property, the volume and staging intervals of truck traffic is not expected to create significant effects upon intersection levels of service, and few additional commuter trips would be generated. However, the EIR will examine transportation impacts.

Air Quality

Air quality could be affected by emissions of dust and diesel exhaust during construction, and by longer-term operational air quality impacts. The project sites are within the jurisdiction of the San Joaquin Valley Air Pollution Control District. San Joaquin County is in nonattainment for the state ambient air quality standard for ozone (one hour) and PM^{10} (particulates 10 microns in diameter and smaller), and is in nonattainment for federal ambient air quality standards for ozone (eight hour), and $PM^{2.5}$ (2.5 microns in diameter and smaller). The EIR will evaluate air quality impacts of the proposed project.

Noise

Use of mechanical equipment and truck traffic associated with construction activities would generate noise and vibration levels typical of building construction, and post-construction operation of the facilities that would be installed under the project would generate noise. It is anticipated that due to the type of activities that would be conducted at both sites and their distance from residences (particularly in the case of Thomas Shaft), noise and vibration impacts would be less than significant. However, the EIR will address potential noise and vibration impacts in the proposed project areas.

Utilities and Public Services

The project would create potential new demands for utility services (e.g., electricity, wastewater, natural gas), and for public services such as police and fire. The EIR will address impacts of the project on utilities and public services.

Other Environmental Issues

The EIR will address other environmental issues, including potential growth-inducing and cumulative effects. The EIR will address the potential of the proposed project to remove an obstacle to growth, and if growth is projected, the EIR will evaluate any secondary impacts of growth. Note that the LLNL Supply Improvements would enable SFPUC to meet existing commitments to LLNL. In its own National

Environmental Policy Act Environmental Impact Statement (EIS) covering its future growth, LLNL anticipated and analyzed the impacts of the connection of Site 300 to the Hetch Hetchy system. No cumulative impacts to water availability for Site 300 and the vicinity were expected.[3]

The EIR will also address whether the proposed project could result in impacts that are significant when combined with the impacts of other SFPUC projects or other non-SFPUC projects occurring in the area at the same time or in the reasonably foreseeable future.

3.2 Alternatives

The EIR will describe and evaluate a reasonable range of alternatives to the proposed project, as required by CEQA. The alternatives would feasibly attain most of the project's basic objectives while simultaneously avoiding or substantially lessening any significant effects of the proposed project. CEQA also requires evaluation of the 'No Project' alternative.

Notice of Preparation of EIR

S.J. Regional Water Quality Improvement

PUBLIC NOTICE

No. 0683

SAN FRANCISCO PLANNING DEPARTMENT NOTICE OF PREPARATION OF AN ENVIRONMENTAL IMPACT REPORT AND NOTICE OF PUBLIC SCOPING MEETING FOR THE SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT.

A Notice of Preparation (NOP) of an Environmental Impact Report (EIR) pursuant to the California Environmental Quality Act (CEQA) and a Notice of Public Scoping Meeting for the above-referenced project, described below, has been issued by the San Francisco Planning Department on May 17, 2007.

Project Description (Case No. 2007.0427E)

The San Francisco Public Utilities Commission (SFPUC) is proposing the San Joaquin Regional Water Quality Improvement Project to improve the disinfection capabilities of the Tesla Portal site and the Thomas Shaft site. Both of these sites are located in unincorporated San Joaquin County. The Tesla Portal Disinfection Station would be located at the Tesla Portal site and includes closing the existing Tesla Portal Hypochlorite Station and the construction and operation of replacement facilities. Also at the Tesla Portal site, the project would include the construction and operation of a new Advanced Disinfection Facility that would pass water by a series of ultraviolet light arrays. At the Thomas Shaft site, the Lawrence Livermore National Laboratory Supply Improvements would upgrade water treatment facilities. This project is part of the Water System Improvement Program,

at this meeting and until the close of business on **June 18, 2007**. Written comments should be sent to the San Francisco Planning Department, Attn: Paul Maltzer, Environmental Review Officer, San Joaquin Pipeline System Project EIR, 1650 Mission Street, Suite 400, San Francisco, CA, 94103-2479 or provided via email to jamie.dean@sfgov.org, or by fax to (415) 558-6409.

PUBLIC NOTICE

SAN FRANCISCO PLANNING DEPARTMENT NOTICE OF PREPARATION OF AN ENVIRONMENTAL IMPACT REPORT AND NOTICE OF PUBLIC SCOPING MEETING FOR THE SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT.

A Notice of Preparation (NOP) of an Environmental Impact Report (EIR) pursuant to the California Environmental Quality Act (CEQA) and a Notice of Public Scoping Meeting for the above-referenced project, described below, has been issued by the San Francisco Planning Department on May 17, 2007.

Project Description (Case No. 2007.0427E)
The San Francisco Public Utilities Commission (SFPUC) is proposing the San Joaquin Regional Water Quality Improvement Project to improve the disinfection capabilities of the Tesla Portal site and the Thomas Shaft site. Both of these sites are located in unincorporated San Joaquin County. The Tesla Portal Disinfection Station would be located at the Tesla Portal site and includes closing the existing Tesla Portal Hypochlorite Station and the construction and operation of replacement facilities. Also at the Tesla Portal site, the project would include the construction and operation of a new Advanced Disinfection Facility that would pass water by a series of ultraviolet light arrays. At the Thomas Shaft site, the Lawrence Livermore National Laboratory Supply Improvements would upgrade water treatment facilities. This project is part of the Water System Improvement Program, which has an overall objective of providing SFPUC customers with optimized solutions with respect to seismic and delivery reliability, cost, water quality, operational flexibility, and environmental impacts.

Public Scoping Meeting and Public Comments
The purpose of the EIR is to provide information about potentially significant adverse effects of the Project. The San Francisco Planning Department will hold a PUBLIC SCOPING MEETING on Wednesday, June 6, 2007 starting promptly at 6:30 PM at the Tracy Golf and Country Club, 35200 South Chrisman Road, Tracy, CA.

The purpose of this meeting is to receive oral comments to assist the San Francisco Planning Department in reviewing the scope and focus of the Project's environmental impact analysis and information to be contained in the EIR. Written comments will also be accepted at this meeting and until the close of business on June 18, 2007. Written comments should be sent to the San Francisco Planning Department, Attn: Paul Maltzer, Environmental Review Officer, San Joaquin Pipeline System Project EIR, 1650 Mission Street, Suite 400, San Francisco, CA, 94103-2479or provided via email to jamie.dean@sfgov.org, or by fax to (415) 558-6409.

About the **San Joaquin Regional Water Quality Improvement Project**, please visit: **www.sfwater.org** or contact:

Mr. Jim Marks, *San Francisco Public Utilities Commission*
415.554.3237 or jmarks@sfwater.org

How To Get There

West: take I-580 E, take CA 132 exit towards Modesto, merge onto CA 132 E, take Chrisman Rd exit, turn right at S Chrisman Rd.

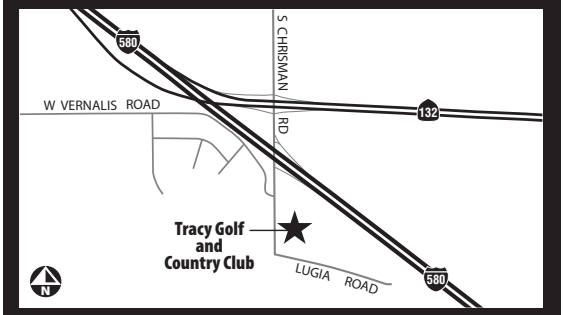
East: take CA 132 W, take the Chrisman Rd exit, turn left at Chrisman Rd.

North: take I-5 S, take exit 449 B and merge onto CA 132 W toward San Francisco, take Chrisman Rd exit, turn left at S Chrisman Rd.

South: take I-5 N, slight left onto I-580 N (towards I-580/Tracy/San Francisco), take Chrisman Rd exit towards CA 132/Tracy, sharp left at S Chrisman Rd.

Public Scoping Meeting

The San Francisco Planning Department will be holding a public scoping meeting to receive comments on the scope and focus of the environmental review for the proposed **San Joaquin Regional Water Quality Improvement Project.**



When: Wednesday, June 6, starting promptly at 6:30 PM

Where: Tracy Golf and Country Club
35200 South Chrisman Road, Tracy, CA 95377

To learn more about the environmental review for the proposed

San Joaquin Regional Water Quality Improvement Project,

and to provide comment on the scope and focus of the environmental review for the proposed project, please attend a

Public Scoping Meeting

Wednesday, June 6th • starting promptly at 6:30 PM

The **San Joaquin Regional Water Quality Improvement Project** is proposed to improve disinfection capabilities at the Tesla Portal and Thomas Shaft sites. At Tesla Portal, the existing Tesla Portal Hypochlorite Station would be closed and replaced with a new Disinfection Station. Also at this site, the new Advanced Disinfection Facility would be constructed and operated. At the Thomas Shaft site, the Lawrence Livermore National Laboratory Supply Improvements would upgrade water treatment facilities to provide potable water to the Lab's Site 300.

ENVIRONMENTAL REVIEW PROCESS

California Environmental Quality Act

Projects require environmental review under the California Environmental Quality Act (CEQA) before they can be considered for approval

For SFPUC projects, CEQA is implemented by the San Francisco Planning Department

CEQA Objectives

- Present environmental impacts of proposed projects
- Identify ways to avoid or reduce environmental impacts
- Support the agency decision-making process
- Encourage public participation
- Enhance interagency coordination

What will the EIR do?

- Provide a detailed description of the project and the existing environment
- Identify potential environmental effects
- Identify ways to avoid or reduce significant environmental effects through mitigation or alternatives to the proposed project

Meeting Purpose

- Hear your comments on the proposed scope of environmental review of the San Joaquin Regional Water Quality Improvement Project
- Help identify the following to be analyzed in depth:
  - *Range of alternatives*
  - *Environmental effects*
  - *Methods of assessment*
  - *Mitigation measures*

PROPOSED SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT

SFPUC Hetch Hetchy Water System

Major Water System Facilities

- **280-plus miles of pipelines**
- **60-plus miles of tunnels**
- **11 reservoirs**
- **5 pump stations**
- **2 water treatment plants**

Water System Improvement Program (WSIP)

- Voter approved November 2002
- More than 70 projects to
  - *Repair, replace and seismically upgrade key water system facilities*
  - *Add new, redundant facilities to ensure system reliability*
  - *Maintain high-quality water*
- SJR Water Quality project one of many WSIP projects

Project Goals and Objectives

- Meet current seismic, safety/fire, and building code standards
- Improve current water quality management capabilities
- Meet United States Environmental Protection Agency's (USEPA's) requirements for reducing *Cryptosporidium* in drinking water
- Meet USEPA requirements for inactivation of *Giardia*
- Fulfill commitment to Lawrence Livermore National Laboratory (LLNL) to supply potable water to Site 300

Existing Tesla Site

Existing Tesla Site

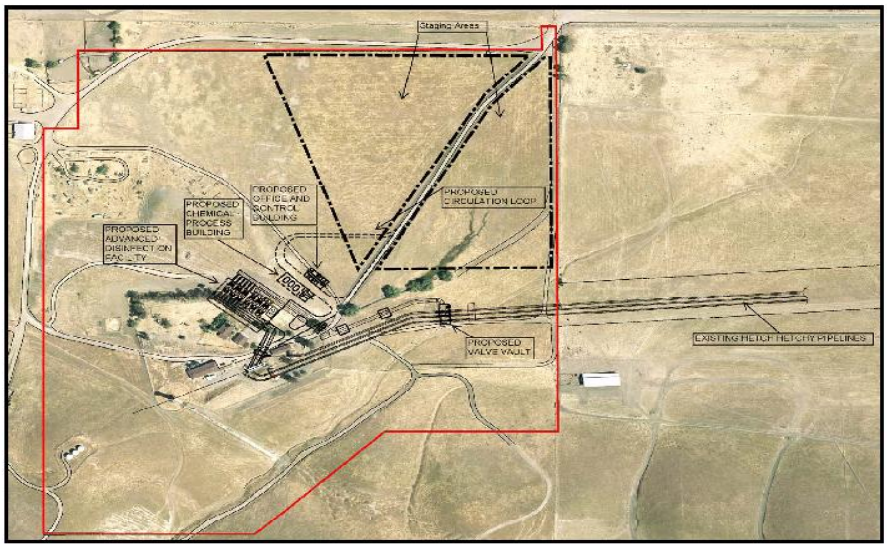
Existing Tesla Facility

- Primary disinfection point for the SFPUC water system
- Disinfectant : Sodium Hypochlorite
- Chemicals stored in two 13,000-gallon tanks and four 4,000-gallon tanks

Existing Tesla Facility (cont'd)

- Valve houses
- Pump house
- Three 20,000-gallon water tanks
- Watershed keeper's cottage
- Chemical delivery 6 loads/week at maximum flow

Proposed Improvements at Tesla



Not To Scale

Project Boundary
Limits of Staging Areas

SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT

Tesla Portal Site Plan

Figure 3

Typical Large UV Reactor System

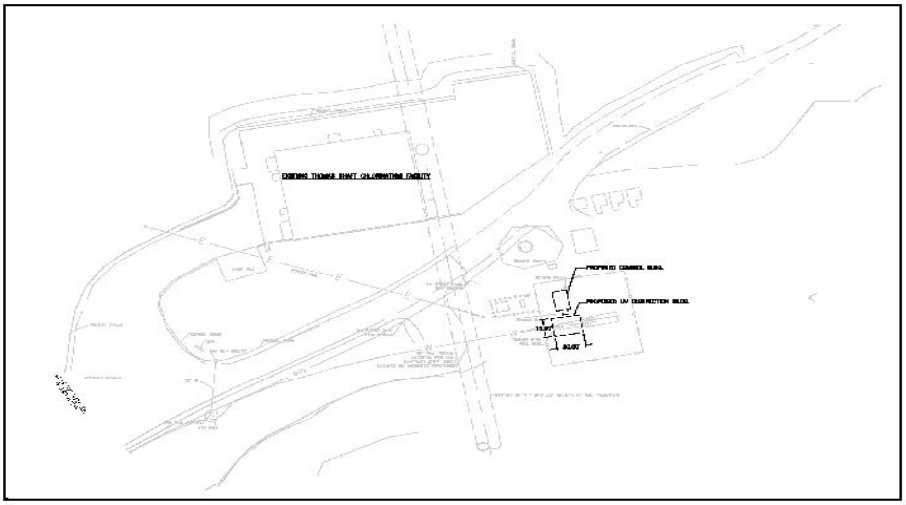
Existing Thomas Shaft – Water Supply Site to LLNL Site 300

Existing Thomas Shaft Facility

- Backup chlorination facility
- Chemical receiving and storage facility
- Three 6,000-gallon Sodium Hypochlorite Tanks

- Pumps
- Water quality analyzer
- Chemical delivery 5-6 loads/year

Proposed Improvements at Thomas Shaft



Not To Scale

SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT

Lawrence Livermore Supply Improvements

Project Schedule

Environmental Review & Permitting: Thru Fall 2008

Improvements at Tesla

Project Design: Spring 2007 thru Summer 2009

Project Construction: Summer 2009 thru Spring 2011

Improvements at Thomas Shaft for LLNL Supply (Site 300)

Project Design: Spring 2008 thru Spring 2010

Project Construction: Spring 2010 thru Fall 2011

Environmental Review Schedule

- Notice of Preparation – May 17, 2007
- Public Scoping Meeting – June 6, 2007
- Scoping Period Ends – June 18, 2007
- Public Review of Draft EIR – 2008
- Release of Final EIR – 2008
- Certification of Final EIR – 2008

PUBLIC COMMENTS

Comment Session Ground Rules

- Submit speaker cards to speak
- Wait until your name is called
- Speak into the microphone and state your name
- Limit comments to 3 minutes
- Use comment forms for more extensive input

Where to Send Comments

- Scoping comments accepted through June 18, 2007
- Send by email to: jamie.dean@sfgov.org
- Send by fax to (415) 558-6409
- Send by U.S. mail to:

The Planning Scoping Meeting was held at the Tracy Golf and Country Club, 35200 South Chrisman Road, Tracy, California, at 6:30 PM on the 6th day of June, 2007.

PLANNING SCOPING MEETING

BY MR. MALTZER:

Again, I'm Paul Maltzer with the Planning Department, in San Francisco. There are essentially two agencies here: The San Francisco Planning Department and the Public Utilities Commission. I'll introduce them in a moment.

This is a Scoping Meeting for The San Joaquin Regional Water Quality Improvement Project and the Environmental Impact Report that we are going to be preparing for the project, and again, I'm going to be describing to you in a little more detail what the purpose of this meeting is, but by and large, we are here to hear from you.

I'm going to try and give you a little bit of information our process. The PUC is going to give you a little information about the project, but mostly the purpose of this meeting is for us to hear from you. . I think we went through the general and accounts keeping. The agenda: I will be introducing some of the people here, and as I described, an overview of the Environmental Review process. I'm going to talk a little bit about what an EIR is all about.

The PUC will describe for you briefly what their project is that's being proposed and then we're going to move on to public comment where you will each have an

opportunity to tell us what you think we need to be addressing in the report that we are going to be producing. That's going to be the meeting tonight.

In terms of introductions, again, I'm Paul Maltzer, the Environmental Review Officer. In the Planning Department, one of our functions is to do the Environmental Review for the City,. There is an office that does that, the
Office of Environmental Review. I head up that office.

Jamie Dean works up that office. She is the staff person, the EIR coordinator. She is the person who is responsible for producing and directing the production of the EIR. We have a few members of the PUC, the Public Utilities Commission, here as well.

Bijan Ahmadzadeh, the Project Manager is here. Robin Breuer, the Environmental Project Manager, Jim Marks, the communications person for the PUC are all here tonight as well.

The Environmental Review process will be very brief. The state law requires that the before decisions are made on projects that we need to examine them for potential consequences, potential physical and environmental impacts as pursuant to the California Environmental Quality Act or CEQA.

You may hear the term CEQA. It stands for California

Environmental Quality Act. It gives us access to produce those reports. Those reports for San Francisco are produced by the Planning Department. That's our role. The Public Utilities Commission's role here is the project sponsor. They have a project they are proposing before the City, the Public Utilities Commission, the Board of Supervisors can take any action on it. The Planning Department needs to complete an Environmental Review, and as part of that Environmental Review process, we engage with the public and get public input.

That's the purpose of this meeting tonight.

The next line, the objectives of CEQA. The main objectives are to disclose potential environmental consequences of a project before decisions are made. It's to inform the decision making process, to look before you leap, essentially, and particularly with regard to physical and environmental impacts.

Another objective of a CEQA process is to identify impacts, to look up for ways that they can be reduced or avoided; typically referred to as mitigation measures. You may hear that term, to find impacts and ways that they can be mitigated.

That information is put together in written reports used by the agencies that make decision on the project.

It's not the only information that may be relevant to them, but is important information that they need to consider before they make the decision, but it is relevant information that they need to consider before they may make a decision. The CEQA process is to ensure that decisions are made out in public with the benefit of public input in conversations with the public.

So, public participation is a large part of the CEQA process and it ensures agency coordination, not just the PUC and the Planning Department, but other agencies that may be involved in the decision making process. It may be Fish and Game or Fish and Wildlife or Army Corps of Engineers or EPA, other agencies that may have decisions to make may also interact with us as we are producing these reports.

What will the EIR do? A project description. One of the key procedures of the EIR if to fully describe the project so that people know what is being proposed, to identify potential environmental effects, again, environmental effect? -- what does that mean? We typically what it means under CEQA law is physical and environmental impacts: Impacts on biology, on the land, air quality, transportation, noise, things of that nature -- information

that many people are interested in with regard to a project or analysis that they're interested in.

What the CEQA process does not report on are sociological or economic issues, but physical and environmental impacts are the focus of the Environmental Review, and to look at ways to avoid or reduce potential impacts that we have identified. That's the nuts and bolts of what an EIR is supposed to do.

The purpose of this meeting is to engage with the public to help us, the Planning Department and our consultants make sure that we are covering the scope of issues that are necessary and important and relevant for us to be discussing.

Although we have expertise in producing environmental documents, we're not necessarily experts on every project area that the neighbors and the public may be more familiar with and it's important to hear from the public what issues they have of concern that we may or may not be aware of to help us focus our study of the EIR.

In addition to that, EIR looks at alternatives to a project. If a project has potential impacts or consequences
are there other possible projects that may still accomplish the
main objectives and avoid the impacts and the EIR is

supposed to address alternatives to the project when there are impacts that we are trying to reduce or avoid.

Okay. Looking at environmental impact, methods of how we do our assessment and mitigation measures, these are in terms of what we are hoping to hear from you tonight would be directions to us or questions that you would like us to investigate in the EIR, that kind of falls under this umbrella, if you will:

The impacts of the project; the possible alternatives to the project; the analytical assessment, the methods that we're using to analyze impacts and what mitigation measures you think may be available.

So, to the extent that your comments are focused on the work we're doing, these are the kinds of comments or questions you should be thinking about in terms of what we would hear from you tonight. So, that's a real kind of brief summary of the CEQA process. So, after this meeting in the days or weeks to come, certainly myself and Jamie are available to answer questions you may have about that. Before I turn it over to the PUC, I just want to make sure you understand the PUC is going to, again, describe the project and then we're going to turn it over to you to hear comments from you.

The Hearing tonight we have a Court Reporter here to take your comments. The meeting tonight is not going to be a question and answer session. You'll be given an opportunity to give us your input which will help us do our EIR, which will help, but in terms of the formal scoping questions, do not have some questions and expect us to answer them tonight. We are going to transcribe all of your comments. Then we are going to be including that thinking in terms of the progress of the Environmental Impact Report.

At the end of your comments tonight, we're still going to be here if you have questions that you would like to talk to us about while we have a conversation, that would also be appropriate at the end of the formal scoping meeting. In terms of your comments, we'll give you about three minutes each to give us your comments. It's not going to be a question and answer session right now.

In order to help you understand what they're proposing, in order to help you understand what questions you may have about the project, the PUC is going to give you a description of what is being proposed.

BY MR. BIJAN AHMADZADEH:

My name is Bijan Ahmadzadeh. I am the Project Manager

for the Tesla Disinfection Site, the Tesla project. It's one project, but the other one is the Thomas Shaft project.

Here, first, I want to thank everyone for attending tonight's meeting on behalf of the project team here.

First of all, basically, I would talk about the Hetch Hetchy water system, about the facilities, the water system improvement program which is the bond measure, which was passed in 2002 and its goals, and the project goals of the San Joaquin Regional Water Project, the existing features of the site, the proposed improvements and then followed by the proposed schedule.

This line it's which is also the front of the building as you entered it, is our system map and the project we're talking about is these two stars here. This is Tesla Portal Disinfection Facility and the advanced Disinfection Facility and the supply line to Lawrence Livermore National Lab.

Next slide: The Hetch Hetchy Water System is comprised of over 200 plus miles of pipe line, 60 plus miles of tunnel resevoirs, pump station and two water treatment plants. The regional system was built over 104 years ago and the greater investments that we made have mostly been back in the twenties, thirties, sixties and seventies and so we haven't really had a major improvement program since

the seventies. So, the bond measure sort of helped us to achieve that goal. The water system improvement was a voter-approved in November 2002. It's comprised of more than seventy projects and its main objective is to repair, replace and seismically upgrade key water facilities, add new redundant facilities to ensure system reliability and maintain high quality water, and the SJR water quality project, which is the project we're talking about tonight, is one of the projects in the WSIP, and the bond measure was directed by the San Francisco Public Utilities Commission and the Board of Supervisors and San Francisco voters and it involves over 28 wholesale partners in Alameda, and
Santa Clara and San Mateo counties.

It has oversight from the State Legislature and also we have oversights from our resource agencies and regulatory agencies that oversee the permitting process for our project.

So, the project goals and objectives which are our goals and objectives for this project is basically meet current seismic, fire safety and building code standards for our current facility that's out there right now, improve the current water management capabilities and also as to meet the U.S. Environmental Protection Agency requirements for reducing Cryptosporidium in drinking

water. That's what they call the long term two enhanced surface water treatment rule, and also meet U.S. EPA requirements for inactivation of Giardia.

Cryptospordium and Giardia are parasites that are commonly found in river and lakes that can cause gastrointestinal diseases and basically our goal here is to provide clean, unfiltered water, again, originating from Hetch Hetchy water reservoir and also to continue to implement our water shed protection measure.

Okay, next slide: This is the existing Tesla site which is over here. It's all San Francisco PUC. It's about 64 acres and this is our primary disinfection facility and the correct use that it is.

Next slide: This is a closer view of the existing facility. We have the our close range tunnel, our existing hypochlorite station, our water keeper's cottage and some valves and pump stations.

Next slide: So, the existing Tesla facility which is right over here, right over past the golf course, this is the primary disinfection point from the San Francisco PUC water system.

The disinfectant that we use is sodium hypochlorite which is a liquid form for chlorine that we inject into the coast range tunnel. The chemical stored in these tanks,

these tanks that you see in this picture, we have two 13,000 gallon tanks and four 4,000 gallon tanks currently, and, basically, the goal of the disinfectant is to inactivate pathogens such as virus and Giardia in the drinking water.

Next slide: The existing facility also has some other features, we have valve houses, pump house, three 20,000 gallon water tanks up on the hill there, a water shed keepers's cottage and we deliver chemical there six loads a week at maximum flow.

Next slide: And the proposed improvements, you can probably get a better view over here is basically staying within the confines of the existing facility or existing right-of-way there.

We are proposing to build a new advanced disinfection facility which is the UV facility in here. We also plan to build a new chlorination facility because the existing building is not to building standard. It is old and it is not safe from seismic reliability and fire protection, and then we'll just have like a new administration building.

So, basically, we'll have the chemical process building, chemical feed equipment, office and control buildings. We'll have some emergency backup power supply. Most of the piping will be below grade. We'll have valve

and valve locks.

We'll have some security improvements of the current facility and we'll have some improvements to the existing road that's right there that leads to the new UV facility.

This is a typical large UV reactor system. Basically, they are like, basically, they are lamps. They consist of individual lamps of what happens with the primary mechanism of the UV disinfection involves light penetrating through the water column and it's basically to inactivate the microorganisms the pathogens, like the Cryptosporidium, the Giardia and it renders them unable to replicate.

The EPA or the USEPA has accepted UV technology to be a feasible treatment approach to disinfecting of drinking water.

The new long term two enhanced water treatment rule, which is what we need to comply with, requires that all unfiltered systems use at least two disinfectants in order to provide multiple barriers.

So, one of the measures would be the UV and the other measure would be the chlorination of the system that we're currently practicing and UV lighting, which we need to be in compliance by March of 2012. That's the new drinking rule.

The other treatment facility we have, which is the Thomas Shaft Facility, which is not too far from this

facility. It's four miles down. It's off of Corral Hollow road. This is the building that's there currently and it's basically --

Next slide: It's basically our backup chlorination facility in case, for some reason, Tesla goes down for some unknown reason, we have a backup facility currently in which we can disinfect our water. Basically, it's a chemical receiving and storage facility.

There's three 6,000 gallon sodium hypochlorite tanks at that facility. There's pumps and water quality analyzer and other appurtenances and we deliver chemical there five to six loads a year at that site.

Next slide: And the proposed improvements we plan to do here is in this little small area across the facility, there are pipes, pumps and they're, I think, Lawrence Livermore built a couple of years back. There's a 10-inch pipe line that leads down into Lawrence Livermore and basically what we're proposing to do here is to construct one duty and one redundant UV system about one point MGD.

We'll have some piping, power supplies and control panel and basically the intent of this project is to meet disinfection requirements to the current rule, which is the surface water treatment rule and the new rule, which is for Cryptosporidium. So, this project would also meet our obligation to Lawrence Livermore Lab to providing potable

water.

Next slide: And this would be a type of facility, this is a small UV facility. It's approximately maybe 300 square feet pad that we propose to put in our facility up there that will feed to the 10-inch water line that is currently existing.

The next slide: Basically, our project schedule is, our environmental review and permitting. We're going to complete that through fall of 2008 and our improvements at Tesla, which is both for the UV and the existing disinfection station, we're going to finish -- start. We've already started early design and we're going to finish in the summer of 2009 and construction is proposed the summer of 2009 through Spring of 2011, and then improvement at Thomas Shaft for the supply line at site 300, our project design schedule is starting at Spring of 08, through spring of 2010 through fall of 2011.

So, this is our baseline schedule. We are all planning to -- we are working on our WSIP schedule some. We might be expediting. This is what we are right now marching into.

Other than that, that pretty much describes very briefly some of the components and plans at both of the facilities.

BY MR. MALTZER:

We are almost at the point where we're going to listen to you. Just a couple of last points: The Environmental Review schedule, what you can anticipate coming from our office: First thing has already come out, this is probably the most important document that we have produced so far on this project and there are copies, if you haven't picked this up and looked at it.

This is Notices of Preparation. This is a description of the project together with our first cut at what we are already anticipating the EIR will be addressing. That latter part comes on the back end of the Notice of Preparation on pages twelve through 16 and let's you know what you will expect in looking at the EIR, but, again, we want to hear from you as well.

Public Scoping Meeting: This is the meeting that we are here today to help us hear from you to focus our opinion about what we need to analyze. The scoping period ends June eighteenth. In terms of written comment to us, you know, another 12 days to receive written comment from you as to what you believe should be in the EIR.

As a practical matter, if we receive comment from you thereafter that is really important that needs to be addressed in the EIR, we are going to have to grapple all that. In all likelihood, it will be included with the EIR, but we also need to get the document published and the

later we receive comment from you, the less attention we can give it. So, it's really important that you can get us your comments as soon as possible, so it's really important that you meet this June 18 deadline. At that point, beyond that date, we and our consultants are going to be busy working on the draft EIR.

So, any comment that we receive after that is going to be harder to address.

In terms of the Environmental Review process for an EIR, there are two key stages for that. The first document we would publish is called a draft EIR. We don't have an exact date for that. Hopefully it will be in 2008, but we're not sure. A draft EIR is our first cut of what we think are the impact of the project, mitigation measures, alternatives, significant impacts of the project.

It's called a draft EIR because it gets circulated for public review and comment in a formal way. There will be a 45-day review period typically and a public hearing at least for our Planning Commission to receive comment on the draft EIR.

You will have at least 45 days to review the draft EIR and to comment on what you think we got wrong, right or that we missed, and then in the EIR process, we're required to produce a second book, a book of comments and responses where we layout all the comments we receive and our

responses to them and any revisions that we have made to the EIR. Those are the two key pieces of the EIR, the draft EIR and the summary of comments and responses.

Once we have finished that, the book is ready to be certified as final. That's also hopefully sometime in 2008, we would be ready to take the EIR the draft and comment and responses to our Planning Commission to certify that we are done, that the City has the information necessary to make a decision about the project and then it would be in the hands of the PUC to make a decision.

So, that's our Environmental Review process and now we're up to the public comment. That's really what we are really here for tonight is to hear your comments about what you think we need to address in the EIR. So, we have public speaker cards. If you want to speak tonight and you haven't filled out a public speaker card, please raise your hand.

Is there anyone else here that either hasn't filled out a card or intends to make a comment here tonight? Okay.

Just the one? Okay.

AUDIENCE: So, can I ask my question now please?

MR. MALTZER: We have a Court Reporter. If you could please just clearly state your name and if you can speak clearly, we had intended to limit comments to three minutes

per speaker so that we wouldn't be here all night, I don't know that we have to strictly adhere to that if you are the only speaker, but again, we would like to hear your comments. Please state your name?

MS. BISCOCHO: My name is LINDA B-I-S-C-O-C-H-O, address 7631 Spearman Drive, Tracy, California 96377. This is my question: You are all from San Francisco Planning Department, right?

MR. MALTZER: Yes. This is not a question -- this is not a question and answer session.

A. Because I came in late.

MR. MALTZER: Yes?

A. So, I am not really kind of sure because it says here this is about the San Joaquin Regional Water Quality. So, this does not have to do with San Joaquin County and all that. It's just the fact of the project because it sits here in San Joaquin county; correct?

MR. MALTZER: Right.

A. That's one of my comments. Now, I have my question. I know this is not a question and answer thing. Is there any chance that we can have your water?

MR. MALTZER: Is that your comment? We are going to transcribe your comment and decide whether that needs to be addressed in the EIR. When this meeting is over, if you would like to have a conversation, you're welcome to do

that, but this is not the purpose of this part of the meeting.

A. I know. I just feel like there is this thing dangling in front of our faces and all we can do is just look at it. We can not even taste it. It's right under our noses, practically, because our house is just walking distance from the pipe that goes underneath my property and I want to know if we can at least, you know, have a chance at or a bid at the water that's passing through our property.

My house is just right across that Chrisman Road and so that is my comment, and this project that you're going to have, how will it impact me as a property owner very close to where this project is going to be? I am not very familiar with EIR, what is it? What are you going to have there? Are you going to have a lot of chlorine? Will it be dissipated in the air? Will it affect the air we breathe in that area there? That is one of the questions that, you know, I really don't know what's going to happen in that project.

MR. MALTZER: Well, again, at the end of this meeting we can have mower of a conversation about that.

A. Okay, thank you.

MR. MALTZER: Are there any other speakers who would

like to address the Board? If you could just state your name for the Court Reporter, thank you

A. Brian Jackman, J-A-C-K-M-A-N. I live right next to the pipe line. So, my question is: Is there any of the pipe lines going to be replaced or is it just specifically the two sites that you're going to be working?

MR. AHMADZADEH: Well, this project is inside your property?

MR. JACKMAN: Through our property, which is where we live in that subdivision. Is there a replacement of the pipe that's going to happen?

MR. AHMADZADEH: No. This project is just the upgrades to the facility within the compound of the Tesla site. There is another project.

MR. JACKMAN: So, this is a separate project from the other one?

MR. MALTZER: Yes.

MR. JACKMAN: There is another one about the pipe lines, itself?

MR. MALTZER: Yes, and then after this meeting, the project manager from that meeting is here, so you can ask him some questions about that if you have some questions about the pipe line.

MR. JACKMAN: Okay. Thank you.

MR. MALTZER: But, this is basically our facility

which we are upgrading in order to meet the USEPA requirements for drinking water, the new rule which has to be complied with by 2012 . Yes, please?

A. My name is Mark Wihl, home owner in Park Country as well. Just two things that I would like to see addressed in the EIR is, you know, dust and traffic impact on the residents in Park Country during construction, since the wind blows directly over our place from where the site would be worked on, and also, we have lived here for 20 years and I don't know if there should be any special evacuation drills or sirens or things if anything went wrong at that plant, but in all the years that I have been here, I haven't heard anything about that, but during that time, what are the hazards to the whole population and how can those hazards be mitigated in the case of a problem?

MR. MR. MALZTER: Thank you. Are there any other comments? Yes, please?

A. See if I can turn my question into a comment. Concern about the overall appearance of this facility, is the new facility going to be taller, bigger, wider, painted bright red? Whatever? Is it going to be to enhance the appearance of our community or is it going to take away from the community?

Is the facility going to be landscaped or things like that? That's my comment and question. The other thing is

tagging on to --

MR. AHMADZADEH: I didn't catch your name.

A. -- concern about the road, because my house is right next to that road. Although, I am moving, I hope, one of these days, but for right now, will the facility be pumping more water and if it's pumping more water will it require more chlorine, and if it requires more chlorine, does that mean more traffic down Vernalis, because I hear those trucks go down all the time and of course I have the concern about the possible spill of chlorine into the air and things like that. So, those are my questions and comments. Charlie Tapia, T-A-P-I-A, 34521 Bernard Road.

MR. MALTZER: Are there any other people who have comments that they would like to make?

I'll just move on, then. Again, I will be here and the PUC will be here to answer questions, if you have some or you would like to have more of a conversation tonight. I would like to remind people that in terms of a formal written comment period, in terms of scoping comments, if at all possible, we would like to receive your comments by June eighteenth and then you can put up the next slide.

You can send comments, you can send comments here to Jamie Dean at SFGOV.ORG or you can send them by fax to our office 415-558-6409, that's the Planning Department, or by U.S. Mail to my attention, Paul Maltzer at the Planning

Department as well, and with that, again, I would also like to repeat Bijan, thank you very much for coming. I'm also pleasantly surprised at how many people do participate in the process and is very helpful to us. I know it's hard for people to take time for their busy days and lives to help us come and do this work, but I appreciate your comments, and again, if you have any interest in receiving the draft EIR, in particular, please make sure that you provide us with the name and an address so that we can send that to you. Thank you very much and with that, I think we're in terms of the formal session, we are done.

Address: L-871; P.O. Box 808

City, State, Zip: Livermore, CA 94550

COMMENTS

The Proposed Project (listed as three separate projects in the WSIP NOP) is supported by Lawrence Livermore National Laboratory's Site 300 Experimental Test Facility in fulfillment of the existing contract between the Department of Energy and the City and County of San Francisco for water service supplied at the Thomas Shaft. Each of these three projects promotes the ability to secure water following a 20 year hiatus for the service anticipated. Improvements were installed more than 17 years ago to assist in water delivery to Site 300 pending final regulatory approvals. In the interim, the Site continues to rely on onsite water wells which present administrative and infrastructure challenges to maintain indefinitely. The early or as-scheduled completion of all interrelated projects portends sufficient and high quality water for the Site's population and multifarious operations. The perceived environmental consequences of this phased undertaking can only be viewed as positive for Site 300. Please continue to progress these related projects expeditiously in meeting the legal obligation established by contract.

BAWSCA

Bay Area Water Supply & Conservation Agency

June 15, 2007

Mr. Paul Maltzer
Environmental Review Officer
San Joaquin Regional Water Quality Improvement Project EIR
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103-2479

Subject: Case No. 2007.0427E – San Joaquin Regional Water Quality Improvement Project; Notice of Preparation of an Environmental Impact Report and Notice of Public Scoping Meeting

Dear Mr. Maltzer,

Thank you for the opportunity to provide the following comments from the Bay Area Water Supply & Conservation Agency (BAWSCA). BAWSCA represents the interests of 25 cities and water districts, and two private utilities, that purchase water wholesale from the San Francisco regional water system. These entities provide water to 1.7 million people, businesses and community organizations in Alameda, Santa Clara and San Mateo counties. The BAWSCA agencies are highly dependent on the SFPUC Regional Water System to provide potable drinking water critical to the health and safety of water customers in the region.

These comments are in response to the Notice of Preparation of an Environmental Impact Report (EIR) dated May 17, 2007 for the San Joaquin Regional Water Quality Improvement Project.

Specific Comments

Section 2.1.2 – Project Components

1. The description of the Advanced Disinfection Facility would be more understandable to the general public if a brief statement were added to define what *Cryptosporidium* is and its regulatory significance.

2. The description of the LLNL Supply Improvements should clarify that *Giardia* inactivation is needed to comply with Surface Water Treatment Rule standards and reducing *Cryptosporidium* is required to comply with Long Term-2 Enhanced Surface Water Treatment Rule standards.

3. The description of the LLNL Supply Improvements would be more understandable to the general public if a brief statement were added to define what *Giardia* is and its regulatory significance.

155 Bovet Road, Suite 302 • San Mateo, CA 94402 • *ph* 650 349 3000 • *fx* 650 349 8395 • www.bawsca.org

4. How big is the proposed control building (shown adjacent to the proposed UV disinfection building) in Figure 4?

5. The LLNL Supply Improvements description should note that electrical consumption will increase with the operation of the UV system. The EIR should examine if electrical upgrades (either onsite or offsite) would be required to support this increase.

Section 2.2 – Project Goal and Objectives

6. The objective for the Advanced Disinfection Facility should emphasize that the project is to comply with federal and state drinking water regulations to meet more stringent regulations. It should be stated that the project is mandatory and to not build it would lead to a violation of the Long Term-2 Enhanced Surface Water Treatment Rule.

7. The objective for the LLNL Supply Improvements should clarify that *Giardia* inactivation is needed to comply with Surface Water Treatment Rule standards and reducing *Cryptosporidium* is to comply with Long Term-2 Enhanced Surface Water Treatment Rule standards.

Section 3.1 – Key Environmental Issues to be Addressed in the EIR

8. The discussion of other environmental issues refers to potential growth-inducing and cumulative effects. This section of the EIR must be consistent with the analysis done for the WSIP Program Environmental Impact Report (PEIR) currently in preparation. Also, information developed in the WSIP PEIR that is used in this EIR should be appropriately referenced.

Thank you for the opportunity to provide these comments on the EIR scoping for the San Joaquin Regional Water Quality Improvement project.

Sincerely,

Nicole Sandkulla

COMMENTS ON NOTICE OF PREPARATION OF AN ENVIRONMENTAL IMPACT REPORT FOR THE SAN JOAQUIN REGIONAL WATER QUALITY IMPROVEMENT PROJECT SCH NO. 2007.0427E

Dear Mr. Maltzer:

We have reviewed the Notice of Preparation (NOP) of an environmental impact report (EIR) for the above referenced project. The proposed project consists of the following three components:

- **Tesla Portal Disinfection Station:** This component includes replacement and upgrade of the existing disinfection facilities at the Tesla Hypochlorite Station;
- **Advanced Disinfection Station:** This component includes installing an ultraviolet (UV) disinfection system into a newly constructed water treatment facility at the Tesla Portal; and,
- **Lawrence Livermore National Laboratory (LLNL) Supply Improvements:** This component includes installing an ultraviolet (UV) disinfection system into a newly constructed water treatment facility at the Thomas Shaft.

The proposed project also includes road improvements, installation of valves and valve vaults, installation of two back up generators, and security upgrades that will benefit the Tesla Portal Disinfection Station and Advanced Disinfection Station facilities.

The objectives for each component of the proposed project include the following:

- **Tesla Portal Disinfection Station:** Replace the outdated chlorination facility at the Tesla Portal with a chlorination facility that will meet current seismic, safety/fire, and building code standards;

- **Advanced Disinfection Station:** Provide a facility that will meet U.S. Environmental Protection Agency (USEPA) requirements for *Cryptosporidium* reduction in drinking water; and,

- **LLNL Supply Improvements:** Provide a facility that will meet USEPA requirements for *Giardia* inactivation, *Cryptosporidium* reduction, so the SFPUC can fulfill a contractual agreement to provide drinking water to LLNL Site 300.

Based on the information provided in the NOP, we offer the following comments. These comments are intended to advise the SFPUC of our concerns, so they may be incorporated into the planning and design process at an early date.

COMMENTS ON BIOLOGICAL RESOURCES

In the NOP, the Biological Resources Subsection of Section 3.1 indicates that there are potential impacts to a wetland at the Tesla Portal Site and that the water source for this wetland is runoff from sampling points at the existing Tesla Portal Disinfection Station. However, there is no indication that a wetland would not occur at the site in the absence of runoff from sampling points. As a result, the wetland should be delineated to determine whether it is part of waters of the U.S under the Clean Water Act (CWA) and/or part of waters of the State under the California Porter-Cologne Water Quality Act. Please note that waters of the State under the Porter-Cologne Act include waters outside federal jurisdiction (e.g. isolated waters under the Supreme Court's SWANCC decision). If the wetland is considered part of waters of the U.S., both a CWA Section 401 water quality certification and a CWA Section 404 Permit from the U.S. Army Corps of Engineers will be necessary. If the wetland is part of the waters of the State but not waters of the U.S., Waste Discharge Requirements will need to be issued. Under either scenario, direct impacts should be avoided to the maximum extent practicable.

Cumulative and indirect impacts of wetlands must also be prevented. Indirect impacts include deposition of sediments; erosion of substratum; additional water (flooding); reduced water supply or flows from natural sources creating a condition of pollution; shading; and watershed degradation.

COMMENTS ON HYDROLOGY, GROUNDWATER AND WATER QUALITY

In the NOP, the Hydrology, Groundwater and Water Quality Subsection of Section 3.1 indicates that the proposed project may affect surface water and groundwater quality through construction activities and creation of permanent impervious surfaces. Recommendations for avoiding impacts to water quality are provided below.

Construction Activities

The proposed project will disturb more than one acre of land during construction. As a result, it must be covered under the State NPDES General Permit for Discharges of Storm Water Associated with Construction Activity (General Permit). This can be accomplished by filing a Notice of Intent (NOI) with the State Water Resources Control Board, Division of Water Quality. Copies of the General Permit and NOI can be obtained from the State

Board's web page, http://www.waterboards.ca.gov/stormwtr/construction.html. The project sponsor must propose and implement control measures that are consistent with the General Permit and with the recommendations and policies of the local agency and the Water Board.

Impervious Surfaces

This project would increase the amount of impervious surfaces and as a result increase the amount of storm water runoff from the site. Central Valley Regional Water Quality Control Board (Water Board) staff recommends the development and implementation of a long term Storm Water Management Plan (SWMP) to protect water quality after construction. Post-construction storm water concerns may include significant changes in the hydrograph of the receiving waters caused by storm water runoff, or discharge of pollution, such as fertilizers, pesticides, petroleum products and animal waste to a waterway. We encourage the use of innovative site designs that reduce impermeable surfaces and incorporate Best Management Practices (BMPs) to protect and treat storm water. These considerations should be incorporated into project design as early in the planning phase as possible.

COMMENTS ON HAZARDS AND HAZARDOUS MATERIALS

In the NOP, the Hazards and Hazardous Materials Subsection of Section 3.1 indicates that the proposed project may encounter contaminated soils and/or groundwater because hazardous materials have been used at both sites in the past. As a result, the EIR should discuss whether there is soil and/or groundwater contamination at the site. If the SFPUC does not know whether soils and/or groundwater are contaminated at the site, a preconstruction site investigation may be necessary to evaluate whether contamination is present at the sites. Any contamination found at the sites should be reported to the Water Board and other responsible agencies and remedied to state and local standards.

The EIR should also include an evaluation of the depth of groundwater and whether groundwater is expected to be encountered. If contact with groundwater is anticipated as a part of the project, the EIR should evaluate how groundwater dewatering will be accomplished. This evaluation should address whether dewatering discharges may be contaminated and whether water quality objectives are exceeded in the groundwater. Poor quality or contaminated water should be discharged to the sanitary sewer, assuming approval can be obtained from the sanitary sewer agency. If approval to discharge to the sanitary sewer cannot be obtained and the water cannot be otherwise disposed to land (e.g., as dust control or irrigation for water that has minimal contamination), then the SFPUC should determine whether the discharge could be covered under the Board's Low Threat General NPDES dewatering permit. The discharger will need to submit the requisite sampling, analysis, treatment plans, etc. as a part of their permit application. Sufficient time for preparation of the plan, applying for the permit, and obtaining coverage should be considered before beginning the project.

The discharger should implement best management practices including sediment and suspended solids removal to ensure that groundwater meets water quality objectives prior to discharge to the storm drain. The discharger should also check with the local municipality to ensure that the discharge will not cause localized flooding or other problems associated with the increased flow.

CONCLUSION

Please contact Xavier Fernandez at 510-622-5685 xafernandez@waterboards.ca.gov at the San Francisco Bay Regional Board office or me at (916) 474-4742 if you have any questions.

Dear Ms. Dean:

The California Department of Transportation (Department) appreciates the opportunity to have reviewed the Notice of Preparation (NOP) of an Environmental Impact Report (EIR) for the proposed San Joaquin Regional Water Quality Improvement Project to be located at the Tesla Portal Site and the Thomas Shaft Site west of the SR-132/I-580 Interchange.

The Department has no comments at this time. When complete, please forward the environmental document for review and comment.

If you have any questions or would like to discuss our comments in more detail, please contact Annette Clark at (209) 948-3909 (e-mail: annette_clark@dot.ca.gov) or me at (209) 941-1921.

Sincerely,

Annette Clark

RE: NOP of an EIR and Notice Of Public Scooping
Tesla Portal – San Joaquin County

Dear Mr. Maltzer:

Thank you for allowing the District to comment on this referral. Following are the recommendations from our Risk & Property, Electrical, Irrigation and Domestic Water Divisions:

Irrigation/ Domestic Water

- No comments at this time.

Risk & Property

- No comments at this time.

Electrical

- The proposed project is located outside the Modesto Irrigation District's electric service area. Therefore the Electrical Division has no specific requirements to the proposed project at this time.

The Modesto Irrigation District reserves its future rights to utilize its property, including its canal and electrical easements and rights-of-way, in a manner it deems necessary for the installation and maintenance of electric, irrigation, agricultural and urban drainage, domestic water and telecommunication facilities. These needs, which have not yet been determined, may consist of poles, crossarms, wires, cables, braces, insulators, transformers, service lines, open channels, pipelines, control structures and any necessary appurtenances, as may, in District's opinion, be necessary or desirable.

If you have any questions, please contact me at 526-7433.

Sincerely,

Celia Aceves
Risk & Property Analyst

Project: San Joaquin Regional Water Quality Improvement Project
Case No. 2007.0427E

Subject: CEQA comments regarding the Notice of Preparation for improvements under the Water System Improvement Program that include: closing the existing Tesla Portal Disinfection Station and the construction of replacement facilities at 9000 W. Vernalis Road and the upgrade of water treatment facilities on Thomas Shaft Road (San Joaquin County APNs 253-160-02, 251-330-10 and 251-170-03)

District Reference No: 200701035

Dear Ms. Dean:

The San Joaquin Valley Unified Air Pollution Control District (District) has reviewed the project referenced above and offers the following comments:

The San Joaquin Valley Air Basin is currently designated as serious non-attainment for Ozone and non-attainment (no classification) for PM2.5. On October 30, 2006, the US EPA found that the San Joaquin Valley had attained the PM10 standard. The US EPA based its determination upon monitoring data demonstrating that the ambient air quality had met the requirements for attainment. The US EPA's finding does not change the District's classification as a serious PM10 non-attainment to attainment area. However, re-designation from serious non-attainment to attainment requires additional documentation and will occur at some future date.

Printed on recycled paper

This project would contribute to the overall decline in air quality due to construction activities in preparation of the site, and ongoing traffic and other operational emissions. The District recommends that the air quality section of the EIR have four main components:

1. **A description of the regulatory environment and existing air quality conditions impacting the area.** This section should be concise and contain information that is pertinent to analysis of the project. The District has several sources of information available to assist with the existing air quality and regulatory environment section of the EIR. The District's "*Guide for Assessing and Mitigating Air Quality Impacts, 2002 Revision*" (GAMAQI) contains discussions regarding the existing air quality conditions and trends of the San Joaquin Valley Air Basin (SJVAB), including those pollutants of particular concern: ozone, PM10, and carbon monoxide. In addition, it provides an overview of the regulatory environment governing air quality at the federal, state, and regional levels. The GAMAQI provides air monitoring data and other relevant information for PM-10 and other pollutants. The current GAMAQI can be found at www.valleyair.org/transportation/ceqa_guidance_documents.htm. The most recent air quality data for the District is Available on the California Air Resources Board (ARB) website at http://www.arb.ca.gov/html/aqe&m.htm. The air quality section of EPA's Region 9 (which includes information on the SJVAB) can be found at http://www.epa.gov/ region09/air/index.html.

2. **Estimates of existing emissions and projected pollutant emissions related to the increase in project source emissions and vehicle use, along with an analysis of the effects of these increases.** The EIR should include the methodology, model assumptions, inputs and results for pollutant emissions. The cumulative impact analyses should consider current existing and planned development both within the project area and in surrounding areas. The EIR needs to address the short term and long term local and regional adverse air quality impacts associated with the operation of construction equipment (ROG, NOx, carbon monoxide [CO], and PM10) and emission generated from stationary and mobile sources. The EIR should identify the components and phases of the project. The EIR should provide emissions projections for the project at the build out of each phase (including ongoing emissions from each previous phase). The most current URBEMIS program may be used to quantify these emissions.

   Ozone Precursors – The District recommends using the regional transportation model to quantify mobile source emissions, but in some cases it may be possible to use the most current URBEMIS program to calculate project area and operational emissions. San Joaquin COG may be able to provide assistance with the regional transportation model. The District recommends using the most current URBEMIS program to calculate project area and operational emissions and to identify mitigation measures that reduce impacts. URBEMIS can be downloaded from http://www.urbemis.com/ or the South Coast Air Quality Management District's website at http://www.aqmd.gov/ceqa/urbemis.html. If the analysis reveals that the emissions generated by this project will exceed the District's thresholds (10 tons per

year for ROG and NOx), this project may significantly impact the ambient air quality if not sufficiently mitigated. The project applicant or consultant is encouraged to consult with District staff for assistance in determining appropriate methodology and model inputs.

Toxic Air Pollutants – The air analysis should discuss District and State regulations for identifying and reducing toxic air pollutants and should describe any potential toxic emissions that would be generated by the project. Potential sources that emit toxic pollutants include project operations, and vehicles (the ARB has designated diesel particulate emissions as a toxic air contaminant). If the project is near existing or planned sensitive receptors, the District should be contacted to determine if the project developer should perform a Health Risk Assessment (HRA). An HRA should include a discussion of the toxic risk associated with the proposed project, including project equipment, operations, and vehicles. The GAMAQI defines the significance levels for toxic impacts as a cancer risk greater than 10 in a million and/or a hazard index (HI) of 1.0 or greater for chronic non-carcinogenic or acute risks.

HRA guidelines promulgated by the California Office of Environmental Health Hazard Assessment (OEHHA) and OEHHA toxicity criteria must be used. In addition, the applicant should also refer to the "*Guidance for Air Dispersion Modeling*" document found on the District's web page for additional guidance. This document can be found at http://www.valleyair.org/busind/pto/Tox_Resources/AirQualityMonitoring.htm.

The District recommends use of the latest version of the Hot Spots Analysis and Reporting Program (HARP) released by ARB for an HRA because it is the only software that is compliant with the OEHHA guidelines.

The project consultant should contact the District to review the proposed modeling approach before modeling begins. For more information on HAPs analyses, please contact Mr. Leland Villalvazo, Supervising Air Quality Specialist, at (559) 230-6000 or hramodeler@valleyair.org.

Carbon Monoxide Hotspot Analysis – Results of the traffic study should be used to identify intersections and corridors with high levels of congestion that may result in a CO hot spot. CO hot spots should be screened using a protocol developed by the Institute of Transportation Studies at University of California Davis entitled Transportation Project-Level Carbon Monoxide Protocol. Locations that are predicted by the CO Protocol to experience high levels of CO should be modeled using the most current CALINE dispersion model. The procedure for using the current EMFAC model to calculate emission factors to be used in the CALINE modeling can be downloaded at the Caltrans Division of Environmental Analysis site http://www.dot.ca.gov/hq/env/air/pages/calinesw.htm.

Odor Analysis – The proposed project should be analyzed to see if it is considered near a location of sensitive receptors (including residences) and if odor is a concern. The procedure outlined in the GAMAQI includes the following:

- Identify the location of sensitive receptors (including residences).
- Compare the distance to the nearest sensitive receptor to the distances in Table 4.2 of the GAMAQI. If the sensitive receptors are further away than the distances given in Table 4.2, no further analysis is required. The results should be documented in the EIR.
- Obtain any odor complaints against the facility or similar facilities from the local District office and the county's environmental health department.
- Review the complaints to determine the location of complainants relative to the facility.
- Identify any sensitive receptors at similar distances.
- Determine if emissions of odoriferous compounds will increase or decrease with implementation of the project.
- Draw any reasonable conclusions as to the probability that the project will generate odor complaints based on this analysis of complaint history.

Note that the emission of odiferous compounds should be mitigated as much as feasible if it is anticipated that the project will have a significant impact. For more information on odor impact analyses, please contact Mr. Leland Villalvazo, Supervising Air Quality Specialist, at (559) 230-6000, or hramodeler@valleyair.org.

3. **Identify and discuss all existing District regulations that apply to the project.** The EIR should identify and discuss all existing District regulations that apply to the project. It would be appropriate to discuss proposed rules that are being developed that would apply to the proposed project. Current rules and regulations are available on the District's website at http://www.valleyair.org/rules/1ruleslist.htm. District rules and regulations are periodically revised, and new regulations are promulgated. The District strongly advises the City of San Francisco to contact the District for any rule updates and new rules when the project development begins. Current District rules and regulations applicable to the proposed project are requirements. Based on the information provided, the project will be subject to the following District rules:

Regulation VIII (Fugitive PM10 Prohibitions) Rules 8011-8081 are designed to reduce PM10 emissions (predominantly dust/dirt) generated by human activity, including construction and demolition activities, road construction, bulk materials storage, paved and unpaved roads, carryout and track out, landfill operations, etc. The District's compliance assistance bulletin for construction sites can be found at www.valleyair.org/busind/comply/PM10/Reg VIII CAB.pdf.

Rule 2201 (New and Modified Stationary Source Review Rule) This rule applies to all new stationary sources and all modifications of existing stationary sources that are subject to the District permit requirements and after construction emit or may emit one or more affected pollutant. For more information regarding the District's permitting process, and to determine if an Authority to Construct (ATC) and Permit to

Operate (PTO) are necessary, the applicant should contact the District's Small Business Assistance Office at (209) 557-6446.

Rule 4002 (National Emission Standards for Hazardous Air Pollutants) In the event that any portion of an existing building will be renovated, partially demolished or removed, the project will be subject to District Rule 4002. Prior to any demolition activity, an asbestos survey of existing structures on the project site may be required to identify the presence of any asbestos containing building material (ACBM). In accordance with CAL-OSHA requirements, a certified asbestos contractor must remove any identified ACBM having the potential for disturbance. If you have any questions concerning asbestos related requirements, please contact the District's Compliance Division at (209) 557-6400 or contact CAL-OSHA at (559) 454-1295. The District's Asbestos Requirements Bulletin can be found online at http://valleyair.org/busind/comply/asbestosbultn.htm.

Rule 4102 (Nuisance) This rule applies to any source operation that emits or may emit air contaminants or other materials. In the event that the project or construction of the project creates a public nuisance, it could be in violation and be subject to District enforcement action.

Rule 4601 (Architectural Coatings) This rule limits volatile organic compounds from architectural coatings by specifying architectural coatings storage, clean up and labeling requirements and applies to any person who supplies, sells, offers for sale, applies, or solicits the application of any architectural coating.

Rule 4623 (Storage of Organic Liquids) This rule limits VOC emissions from tanks used to store organic liquids and applies to any tank with a capacity of 1,100 gallons or greater in which any organic liquid is placed, held, or stored.

Rule 4702 (Internal Combustion Engines – Phase 2) This rule applies to any internal combustion engine with a rated brake horsepower greater than 50 horsepower (for example, a standby generator fueled by diesel).

4. **Identify and discuss all feasible measures that will reduce air quality impacts generated by the project.** "Feasible" means "capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, legal, social, and technological factors: (California Code of Regulations (CCR § 15364)). CEQA requires that EIRs "describe measures which could minimize significant adverse impacts" (CCR §15126(c)). Additionally, the CCR requires that "a public agency should not approve a project as proposed if there are feasible alternatives or mitigation measures that would substantially lessen any significant effects that the project would have on the environment " (CCR § 15021(a)(2)). For each potential adverse impact, mitigation measures should be identified to reduce impacts below air quality threshold levels of significance. Therefore, the EIR should identify which mitigation measures will be included in the project, and how each mitigation measure will be implemented. The reduction of air

quality impacts from implementation of mitigation measures should be quantified to the extent possible. If a measure cannot be quantified a qualitative discussion should be provided explaining the benefits of the proposed mitigation measure. The EIR should discuss how project design modifications could reduce project impacts

District staff is available to meet with you and/or the applicant to further discuss the regulatory requirements that are associated with this project. If you have any questions or require further information, please call Jessica Willis at (559) 230-5818 and provide the reference number at the top of this letter.

Sincerely,

David Warner

RE: Notice of Preparation of EIR
San Joaquin Regional Water Quality Improvement Project

Dear Mr/Ms. Dean,

The Tuolumne Band of Me-Wuk Indians would like to provide written comments for the scoping for the City and County of San Francisco's San Joaquin Regional Water Quality Improvement Project. The project has the potential to affect cultural resources, including archaeological sites, burial areas, and plant gathering areas. We know of human remains near the area, along with other important resources. Further, there is some potential for buried cultural deposits, not obvious on the surface, and we suggest you may need to hire a cultural resources firm who conducts archaeological research as well as ethnographic research and geoarchaeology. We request that said qualified firm conduct a cultural resources survey of the impact area, and that they contact us for discussion and further

Sincerely,

Stanley R Cox

APPENDIX B

WSIP PEIR Reference Chapters

Overview and Introduction

As discussed in this Environmental Impact Report (EIR), the proposed project is part of the San Francisco Public Utilities Commission's (SFPUC) Water System Improvement Program (WSIP). The San Francisco Planning Department prepared a Draft Program Environmental Impact Report (PEIR) on the WSIP, which was published on June 29, 2007. After responding to public comments on the Draft PEIR, the Final PEIR was certified by the San Francisco Planning Commission on October 30, 2008 (Motion No. 17734). On that same day, the revised WSIP (known as the "Phased WSIP Variant" in the Final PEIR) was adopted by the SFPUC (Resolution 08-0200).

Because the proposed project is a component of the WSIP, it would contribute to the impacts that would occur with implementation of the WSIP's water supply strategy, including its growth-inducement impacts. These impacts are summarized in the main body of this EIR in the Executive Summary and in Section 4.1, Approach to Analysis, of this EIR. This appendix supplements the WSIP impact summaries by including the actual text from the Draft and Final PEIR on the WSIP's water supply impacts.

Due to the timing of publication of this EIR, certification of the Final PEIR, and adoption of the WSIP, this appendix was assembled to present information on the impacts of the WSIP's water supply strategy and also to correct some of this information in response to comments on the Draft PEIR, as set forth in the Final PEIR. Specifically, this appendix includes the actual text in the Draft and Final PEIR on the originally proposed and the revised, adopted WSIP along with other information and text changes from the Final PEIR relevant to the WSIP's water supply strategy as it relates to the proposed project.

Contents of this Appendix

Text from the Draft PEIR on the WSIP

This appendix contains the following text on the WSIP's water supply impacts from the Draft PEIR:

- **Chapter 5 (Volume 3 of the PEIR):** This chapter evaluates the potential environmental impacts of the WSIP's water supply strategy and regional water system operations. The impact discussion is organized by watershed and related drainages and reservoirs.

- **Chapter 7 (Volume 4 of the PEIR):** This chapter analyzes the WSIP's growth inducement potential and associated secondary effects of growth impacts.

- **Chapter 9 (Volume 4 of the PEIR):** This chapter presents and evaluates the alternatives to the originally proposed WSIP. In particular, it evaluates alternative water supply strategies that could meet most of the basic objectives of the WSIP.

- **Appendix E (Volume 5 of the PEIR):** This appendix supplements the information contained in Chapter 7 of the Draft PEIR on growth inducement impacts.

Text from the Final PEIR on the WSIP

In response to comments on the Draft PEIR, the SFPUC proposed several changes to the WSIP. These changes are detailed in the Final PEIR along with the environmental effects of the revised program. Therefore, this appendix also contains the following text from the Final PEIR on the WSIP:

- **Sections 13.2, 13.3, and 13.4 (Chapter 13, Volume 7a of the PEIR):** These sections describe changes in the WSIP that have been proposed by the SFPUC since publication of the Draft PEIR. The SFPUC has proposed revisions to the WSIP in three areas, either in response to comments received on the Draft PEIR or as part of its ongoing system operations and planning. These revisions include: (1) changes in the project descriptions of two WSIP facility improvement projects (both of which help reduce impacts associated with the projects as originally proposed) which affect overall system operations; (2) updated water system assumptions and corresponding updates in the system modeling and results; and (3) development of the Phased WSIP Variant, a "hybrid" program that is a combination of the proposed program and one of the alternatives analyzed in the Draft PEIR. The environmental impacts of the revised WSIP are also described.

Master responses provide comprehensive discussions to respond to select sets of issues that received multiple comments. The following master responses are included in this appendix to clarify the description of the WSIP and its impacts:

- 14.3 – Master Response on Proposed Dry-Year Water Transfer (Chapter 14, Volume 7a of the PEIR): This master response explains the dry-year transfer component of the adopted WSIP.

- 14.5 – Master Response on Water Resources Modeling and Appendix O (Chapter 14, Volume 7a of the PEIR): This master response addresses questions about the water resources model used for the impact analysis of WSIP. It references "Appendix O," which is also included as part of this appendix.

- 14.9 – Master Response on Alameda Creek Fishery Issues (Chapter 14, Volume 7a of the PEIR): This master response addresses comments on the adequacy of the impact analysis and mitigations with respect to the WSIP's effects on the steelhead fishery in Alameda Creek. It describes in detail the changes that were incorporated into two WSIP facility improvement projects: the Calaveras Dam Replacement Project and the Alameda Creek Fishery Enhancement Project.

- 14.10 – Master Response on Modified WSIP Alternative (Chapter 14, Volume 7a of the PEIR): This master response addresses the issues commenters raised on the Modified WSIP Alternative, which was identified in the Draft PEIR as the environmentally superior alternative.

- 14.11 – Master Response on Climate Change (Chapter 14, Volume 7a of the PEIR): This master response addresses issues raised by commenters concerning the impacts of the WSIP on climate change and global warming.

Chapters 5, 7, and 9 of the Draft PEIR on the WSIP are included in this appendix as described above. Several changes were made to these chapters in the Final PEIR. This section details these changes.

- **16 – Staff-initiated Text Changes for Chapters 5, 7, and 9 (Volume 7b of the PEIR):** This section contains text changes to the Draft PEIR that resulted from: (1) changes made in response to comments received on the Draft PEIR; (2) changes that reflect the WSIP revisions; or (3) changes to correct errors or to clarify information presented in the Draft PEIR. Where a response to a comment includes a change to the text of the Draft PEIR, the text changes are shown in underline for additions and ~~strikethrough~~ for deletions.

The Draft and Final PEIR on the WSIP may be reviewed in its entirety at the offices of the San Francisco Planning Department, 1650 Mission Street, Suite 400, San Francisco, CA 94103.

Volume 1 (*bound separately*)

Glossary
Summary
1. Introduction
2. Existing Regional Water System
3. Program Description

Volume 2 (*bound separately*)

4. WSIP Facility Projects – Setting and Impacts

Volume 3

5. WSIP Water Supply and System Operations – Setting and Impacts

5.1	Overview	5.1-1
5.1.1	Introduction	5.1-1
5.1.2	Chapter Organization	5.1-4
5.1.3	Proposed Water Supply Option and System Operations	5.1-4
5.1.4	Approach to the Analysis	5.1-7
5.1.5	Impact Significance Determination	5.1-18
5.2	Plans and Policies	5.2-1
5.2.1	Overview	5.2-1
5.2.2	Regulatory Framework	5.2-1
5.2.3	Relevant Plans, Policies, and Planning Actions	5.2-14
5.2.4	Plan Consistency Evaluation	5.2-27
5.3	Tuolumne River System and Downstream Water Bodies	5.3.1-1
5.3.1	Stream Flow and Reservoir Water Levels	5.3.1-1
5.3.2	Geomorphology	5.3.2-1
5.3.3	Surface Water Quality	5.3.3-1
5.3.4	Surface Water Supplies	5.3.4-1
5.3.5	Groundwater	5.3.5-1
5.3.6	Fisheries	5.3.6-1
5.3.7	Terrestrial Biological Resources	5.3.7-1
5.3.8	Recreational and Visual Resources	5.3.8-1
5.3.9	Energy Resources	5.3.9-1

Appendices

A. Notice of Preparation / Scoping Report A-1
B. WSIP Initial Study Checklist B-1
C. WSIP Facility Improvement Project Information C-1
D. Biological Resources: Special Status Species in Alameda and Peninsula Watersheds D-1
E. Growth Inducement Potential and Supporting Information E-1
F. Noise and Traffic Background Data F-1
G. Hazardous Materials G-1
H. Modeling Analysis – Water Supply and System Operations H-1
H1. Hydrologic Modeling Report
H2. Hydrologic Modeling – Supporting Information
H3. Temperature Modeling Report
I. Report Preparers I-1

List of Figures

5.1-1 Overview of Water Supply Watersheds in the SFPUC Regional Water System 5.1-2
5.1-2 Annual Average Historical and Projected Future Customer Purchase Requests 5.1-6
5.1-3 Approach to Impact Analysis on Water Resources 5.1-8
5.1-4 Water Supply Sources and Shortages – Existing Conditions 5.1-19
5.1-5 Water Supply Sources and Shortages – 2030 WSIP Conditions 5.1-20
5.2-1 Tuolumne River, Wild and Scenic River Designation 5.2-9
5.3.1-1a Tuolumne River Watershed, Headwaters to Don Pedro Reservoir 5.3.1-3
5.3.1-1b Tuolumne River Watershed, Don Pedro Reservoir to San Joaquin River 5.3.1-4
5.3.1-2 Tuolumne River Schematic Showing Water and Hydropower Facilities 5.3.1-6
5.3.1-3 Hetch Hetchy Reservoir, Historical Water Levels, 1989 to 2005 5.3.1-7
5.3.1-4 Lake Lloyd, Historical Water Levels, 1989 to 2005 5.3.1-9
5.3.1-5 Lake Eleanor, Historical Water Levels, 1989 to 2005 5.3.1-10
5.3.1-6 Don Pedro Reservoir, Historical Water Levels, 1989 to 2005 5.3.1-11
5.3.1-7 San Joaquin River Watershed 5.3.1-15
5.3.1-8 Average Monthly Storage Volume, Hetch Hetchy Reservoir 5.3.1-22
5.3.1-9 Hetch Hetchy Storage and Releases to the Tuolumne River 5.3.1-23
5.3.1-10 Hetch Hetchy Reservoir Storage and Inflow, Calendar Year 1999 5.3.1-28
5.3.1-11 Average Monthly Storage Volume, Don Pedro Reservoir 5.3.1-31
5.3.1-12 Don Pedro Storage and La Grange Releases to the Tuolumne River 5.3.1-33
5.3.1-13 Don Pedro Reservoir Storage and Inflow, Calendar Year 2000 5.3.1-37
5.3.3-1 Tuolumne River Water Temperature at River Mile 43.4 5.3.3-4
5.3.3-2 Typical Summertime Water Temperature Gradient in Hetch Hetchy and Don Pedro Reservoirs 5.3.3-5
5.3.3-3 Longitudinal Profile of Simulated Mean Daily Water Temperature from La Grange Dam to San Joaquin River, June 1993 5.3.3-18
5.3.3-4 Longitudinal Profile of Simulated Mean Daily Water Temperature from La Grange Dam to San Joaquin River, June 1999 5.3.3-19
5.3.8-1 Principal Recreational Resources Tuolumne River System 5.3.8-2
5.3.8-2 Whitewater Rafting Condition Thresholds for the Cherry Creek Run 5.3.8-6

Page

List of Figures (continued)

5.3.8-3 Whitewater Rafting Condition Thresholds for the Lumsden Run 5.3.8-8
5.3.8-4 Example of a Pulse and Release for Whitewater Recreation 5.3.8-9
5.3.8-5 Don Pedro Reservoir Annual Visitation 5.3.8-17
5.3.8-6 Don Pedro Reservoir Average Annual Reservoir Depth and Recreational Uses 5.3.8-26
5.4.1-1 Alameda Creek Drainage Areas 5.4.1-2
5.4.1-2 Alameda Watershed Facilities 5.4.1-5
5.4.1-3 Calaveras Reservoir, Historical Water Levels, 1998 to 2006 5.4.1-8
5.4.1-4 San Antonio Reservoir, Historical Water Levels, 1998 to 2006 5.4.1-15
5.4.1-5 Calaveras Storage and Releases to Calaveras Creek 5.4.1-20
5.4.1-6 Reservoir Storage Volume, Annual Average Calaveras Reservoir 5.4.1-21
5.4.1-7 Chronological Modeled Release of Water below Calaveras Dam 5.4.1-23
5.4.1-8 Flows in Alameda Creek below the Diversion Dam 5.4.1-26
5.4.1-9 Alameda Creek Above and Below Diversion Dam – Flow Rates Upstream and Downstream of Tunnel during "Wet" Water Years 5.4.1-28
5.4.1-10 Alameda Creek Above and Below Diversion Dam – Flow Rates Upstream and Downstream of Tunnel During "Above-Normal" Water Years 5.4.1-29
5.4.1-11 Alameda Creek above and below Diversion Dam – Real-Time Flow Rates vs Daily Mean Flows 5.4.1-30
5.4.1-12 Alameda Creek below Calaveras Creek Confluence 5.4.1-31
5.4.1-13 Flow in Alameda below the Calaveras Creek Confluence 5.4.1-34
5.4.1-14 Chronological Operation of San Antonio Reservoir 5.4.1-37
5.4.1-15 San Antonio Reservoir Releases to San Antonio Creek 5.4.1-38
5.4.1-13 Chronological Flows in Alameda Creek at the Confluence with San Antonio Creek 5.4.1-41
5.4.3-1 Temperature Profiles for Calaveras Reservoir, 1998 5.4.3-2
5.4.4-1 Sunol Groundwater Basin Groundwater Elevations and Flow Directions 5.4.1-3
5.4.5-1 Potential Barriers to Fish Migration in Alameda Creek Watershed 5.4.5-8
5.5.1-1 Peninsula Watersheds and Drainages 5.4.1-2
5.5.1-2 Peninsula Watershed Facilities and Flow Locations Analyzed 5.5.1-3
5.5.1-3 San Andreas Reservoir, Historical Water Levels, 1998 to 2006 5.5.1-6
5.5.1-4 Crystal Springs Reservoir, Historical Water Levels, 1998 to 2006 5.5.1-7
5.5.1-5 Pilarcitos Creek Watershed 5.5.1-8
5.5.1-6 Pilarcitos Reservoir, Historical Water Levels, 1998 to 2006 5.5.1-10
5.5.1-7 Reservoir Storage Volume, Annual Average Crystal Springs Reservoir 5.5.1-15
5.5.1-8 Crystal Springs Storage and Release to San Mateo Creek 5.5.1-17
5.5.1-9 Reservoir Storage Volume, Annual Average San Andreas Reservoir 5.5.1-18
5.6-1 Westside Groundwater Basin Monitoring Network and Major Production Wells 5.6-2
5.6-2 Regional Cross Section through Westside Groundwater Basin 5.6-3
5.6-3 Historical Pumping in South Westside Groundwater Basin 5.6-7
5.6-4 Recent Municipal Pumping in Westside Groundwater Basin 5.6-9
5.6.5 Contours of Equal Groundwater Elevations, Shallow Aquifer, Spring 2005 5.6-11
5.6.6 Contours of Equal Groundwater Elevations Primary Production Aquifer, Spring 2005 5.6-12
5.6.7 Long-Term Lake Level Hydrograph Lake Merced (South Lake) 5.6-14
5.7-1 Current and Unimpaired Average Monthly Flows in the Tuolumne River below Hetch Hetchy Reservoir 5.7-25

Page

5.7-2 Current and Unimpaired Average Monthly Flows in the Tuolumne River below La Grange Dam 5.7-35
5.7-3 Future Projects in the Alameda Creek Watershed Considered in the Cumulative Analysis 5.7-55
5.7-4 Future Projects in the Peninsula Watershed Considered in the Cumulative Analysis 5.7-71
5.7.5 Projected Decreases in Snow Pack in the Hetch Hetchy Watershed Due to Climate Change, 2000 to 2050 5.7-95

List of Tables

5.1-1 Modeling Assumptions Used in the CEQA Analysis 5.1-12
5.1-2 HH/LSM Output Parameters 5.1-15
5.2-1 Applicable Federal, State, and Local Statutes and Agreements 5.2-3
5.2-2 Summary of General Plan Policies of Counties with Surface Water and Groundwater Resources Potentially Affected by the Proposed WSIP Water Supply and System Operations 5.2-26
5.3.1-1 Mean Monthly Stream Flows at Selected Locations on Waterways Potentially Affected by the WSIP 5.3.1-12
5.3.1-2 Schedule of Average Daily Minimum Required Releases to Support Fisheries Below O'Shaughnessy Dam 5.3.1-13
5.3.1-3 Minimum Instream Flow Requirements – Tuolumne River at La Grange Bridge 5.3.1-14
5.3.1-4 Summary of Impacts – Stream Flow in the Tuolumne River System and Downstream Waterbodies 5.3.1-21
5.3.1-5 Estimated Average Monthly Flows for the Tuolumne River below O'Shaugnesssy Dam under Various Conditions 5.3.1-26
5.3.1-6 Estimated Average Monthly Flows for the Tuolumne River below La Grange under Various Conditions 5.3.1-35
5.3.2-1 Summary of Impacts – Geomorphology of the Tuolumne River System and Downstream Waterbodies 5.3.2-6
5.3.3-1 Summary of Temperature Data, Hetch Hetchy Reservoir 5.3.3-2
5.3.3-2 Maximum Summer–Fall Water Temperatures in the Tuolumne River from La Grange Dam to Modesto 1996–2004 5.3.3-3
5.3.3-3 Water Quality Data Summary, San Joaquin River at Vernalis Above Normal (2000)/Dry (2002) 5.3.3-6
5.3.3-4 Water Quality Characteristics at Selected Stations within the Delta 5.3.3-8
5.3.3-5 Water Quality Data Summary, Banks Pumping Plant Above Normal (2000)/Dry (2002) 5.3.3-8
5.3.3-6 Pertinent Water Quality Objectives for the San Joaquin River Basin 5.3.3-10
5.3.3-7 Section 303(d) List of Impaired Water Bodies 5.3.3-11
5.3.3-8 Summary of Impacts – Surface Water Quality in the Tuolumne River System and Downstream Waterbodies 5.3.3-14
5.3.3-9 Average Flows for Conditions Where Water Temperatures Could Be Adversely Affected (Tuolumne River Below Hetch Hetchy) 5.3.3-16
5.3.3-10 Comparison of Storage, Cool Water Pool Volumes, and Depth to Thermocline for Don Pedro Reservoir under Existing Conditions and with the WSIP 5.3.3-17
5.3.4-1 Flow and Water Quality Objectives for San Joaquin River at Vernalis 5.3.4-3
5.3.4-2 Flow Objectives for Sacramento-San Joaquin Delta 5.3.4-4
5.3.4-3 Summary of Impacts – Surface Water Supplies of Downstream Users 5.3.4-5

Page

List of Tables (continued)

5.3.4-4 Average Monthly Changes in Tuolumne River Flow below La Grange Dam Attributable to the WSIP 5.3.4-7
5.3.4-5 Recorded San Joaquin River Flow at Vernalis (1969 – 2002) 5.3.4-8
5.3.5-1 Summary of Impacts – Groundwater Bodies in the Tuolumne River Watershed 5.3.5-4
5.3.6-1 Fish Species Known to Inhabit Tuolumne River Tributaries, Hetch Hetchy and Don Pedro Reservoirs, Lake Lloyd, and Lake Eleanor 5.3.6-5
5.3.6-2 Tuolumne River Spawning Survey Summary 5.3.6-15
5.3.6-3 Non-Salmonid Species Present in the Lower Tuolumne River 5.3.6-19
5.3.6-4 Summary of Impacts – Fisheries in the Tuolumne River System and Downstream Waterbodies 5.3.6-25
5.3.7-1 Potential for Occurrence of Key Special-Status Plants and Plant Species of Concern in the WSIP Tuolumne Watershed Program Area 5.3.7-6
5.3.7-2 Potential for Occurrence of Key Special-Status Animals and Animal Species of Concern in the WSIP Tuolumne Watershed Program Area 5.3.7-7
5.3.7-3 Summary of Impacts – Terrestrial Biological Resources in the Tuolumne River Watershed 5.3.7-19
5.3.8-1 Whitewater Rafting Condition Thresholds for the Cherry Creek Run 5.3.8-6
5.3.8-2 Whitewater Rafting Condition Thresholds for the Lumsden Run 5.3.8-7
5.3.8-3 Annual Boater Use on the Tuolumne River (1984–2005) 5.3.8-11
5.3.8-4 Private Boater Use by Month (1990–2002) 5.3.8-13
5.3.8-5 Summary of Impacts – Recreational and Visual Resources in the Tuolumne River System 5.3.8-22
5.3.8-6 Estimated Average Monthly Flows in the Tuolumne River Immediately below the Cherry Creek Confluence under Various Conditions 5.3.8-29
5.3.8-7 Flow in the Tuolumne River Immediately below the Cherry Creek Confluence under Existing Conditions 5.3.8-30
5.3.8-8 Flow in the Tuolumne River Immediately below the Cherry Creek Confluence with the WSIP 5.3.8-31
5.3.9-1 Summary of Impacts – Energy Resources along Tuolumne River System 5.3.9-2
5.4.1-1 Areas of Alameda Creek Sub-Watersheds in the WSIP Study Area 5.4.1-4
5.4.1-2 Historical Calaveras Reservoir Spillway Releases (Uncontrolled) 5.4.1-10
5.4.1-3 Approximate Calaveras Cone Valve Releases Since 2001 (Controlled) 5.4.1-11
5.4.1-4 Historical Record of Alameda Creek Flow above the Diversion Dam 5.4.1-12
5.4.1-5 Alameda Creek Number of Days Exceeding 650 cfs Flow, Measures above the Diversion Dam – 1997 to 2007 5.4.1-13
5.4.1-6 Summary of Impacts – Stream Flow in Alameda Creek Watershed Streams and Reservoirs 5.4.1-18
5.4.1-7 Estimated Average Monthly Releases from Calaveras Reservoir to Calaveras Creek 5.4.1-24
5.4.1-8 Estimated Average Monthly Flow in Alameda Creek below the Calaveras Creek Confluence 5.4.1-32
5.4.1-9 Minimum Flows below the Confluence of Alameda and Calaveras Creeks 5.4.1-33
5.4.1-10 Estimated Average Monthly Releases from San Antonio Reservoir to San Antonio Creek 5.4.1-40
5.4.1-11 Estimated Average Monthly Flow in Alameda Creek below San Antonio Creek Confluence 5.4.1-42

Page

List of Tables (continued)

5.4.2-1 Summary of Impacts – Geomorphology of Alameda Creek Watershed 5.4.2-3
5.4.3-1 Summary of Water Quality in Calaveras Reservoir 5.4.3-3
5.4.3-2 Summary of Water Quality in San Antonio Reservoir 5.4.3-4
5.4.3-3 Summary of Temperature Data, Alameda Creek near Sunol, 1997–2005 5.4.3-5
5.4.3-4 Summary of TDS Data, Alameda Creek near Sunol, 1997–2005 5.4.3-6
5.4.3-5 Alameda Drainage Water Quality Regulations 5.4.3-7
5.4.3-6 Summary of Impacts – Surface Water Quality in Alameda Creek Watershed Streams and Reservoirs 5.4.3-7
5.4.4-1 Summary of Impacts – Groundwater Bodies in Alameda Creek Watershed 5.4.4-6
5.4.5-1 Fish Species Observed in the Alameda Creek Watershed 5.4.5-13
5.4.5-2 Summary of Impacts – Fisheries in Alameda Creek Watershed Streams and Reservoirs 5.4.5-17
5.4.6-1 Potential for Occurrence of Natural Communities in the Alameda Watershed WSIP Program Area 5.4.6-4
5.4.6-2 Potential for Occurrence of Key Special-Status Plants and Plant Species of Concern in the WSIP Alameda Watershed Program Area 5.4.6-7
5.4.6-3 Potential for Occurrence of Key Special-Status Animals and Animal Species of Concern in WSIP Alameda Watershed Program Area 5.4.6-8
5.4.6-4 Summary of Impacts – Terrestrial Biological Resources in the Alameda Creek Watershed 5.4.6-15
5.4.7-1 Summary of Impacts – Recreational and Visual Resources in the Alameda Creek Watershed 5.4.7-5
5.5.1-1 Summary of Impacts – Stream Flow in San Francisco Peninsula Streams 5.5.1-14
5.5.2-1 Summary of Impacts – Geomorphology of San Francisco Peninsula Streams and Reservoirs 5.5.2-3
5.5.3-1 Water Quality in San Mateo Creek below Crystal Springs Reservoir 5.5.3-3
5.5.3-2 Summary of Impacts – Water Quality of San Francisco Peninsula Streams and Reservoirs 5.5.3-5
5.5.4-1 Summary of Groundwater Quality Parameters, Lower Pilarcitos Creek Basin 5.5.4-2
5.5.4-2 Summary of Impacts – Groundwater Bodies in Peninsula Watershed 5.5.4-2
5.5.5-1 Summary of Impacts – Fisheries in San Francisco Peninsula Streams and Reservoirs 5.5.5-6
5.5.6-1 Potential for Occurrence of Natural Communities in and near the WSIP in the Peninsula Watershed 5.5.6-3
5.5.6-2 Key Special-Status Plants and Plant Species of Concern in the WSIP Peninsula Watershed Operational Area 5.5.6-6
5.5.6-3 Key Special-Status Animals and Animal Species of Concern in the WSIP Peninsula Watershed Operational Area 5.5.6-7
5.5.6-4 Summary of Impacts – Terrestrial Biological Resources in the Peninsula Watershed 5.5.6-14
5.5.7-1 Summary of Impacts – Recreational and Visual Resources in the Peninsula Watershed 5.5.6-5
5.6-1 Summary of Impacts – Westside Groundwater Basin 5.6-23
5.7-1 Projects Which May Contribute to Cumulative Effects 5.7-14
5.7-2 Summary of Cumulative Impacts in the Tuolumne River System and Downstream Water Bodies Related to WSIP Water Supply and System Operations 5.7-23

Page

List of Tables (continued)

5.7-3	Estimated Flood Peaks in the Tuolumne River below Hetch Hetchy Reservoir	5.7-26
5.7-4	Hetch Hetchy Reservoir Modeled Minimum Stream Releases with Discretionary Flow Fishery Releases	5.7-30
5.7-5	Cumulative Effects on the Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs	5.7-33
5.7-6	Estimated Flood Peaks in the Tuolumne River below La Grange Dam	5.7-35
5.7-7	Flow in the Tuolumne River Below La Grange Dam – Exisiting Condition Plus Infiltration Gallery Project	5.7-40
5.7-8	Flow in the Tuolumne River below La Grange Dam – Existing Condition Plus Infiltration Gallery Project	5.7-41
5.7-9	Cumulative Effects on the Tuolumne River Between La Grange Dam and the San Joaquin River	5.7-43
5.7-10	Flow in the Tuolumne River below La Grange Dam – WSIP Plus Infiltration Gallery Project	5.7-44
5.7-11	Flow in the Tuolumne River below La Grange Dam – WSIP Plus Infiltration Gallery Project	5.7-45
5.7-12	Cumulative Effects on the San Joaquin River, Stanislaus River, and Delta	5.7-50
5.7-13	Future Projects in the Alameda Creek Watershed Considered in the Cumulative Analysis	5.7-57

CHAPTER 5
WSIP Water Supply and System Operations – Setting and Impacts

Chapter 5 Sections

5.1 Overview

5.2 Plans and Policies

5.3 Tuolumne River System and Downstream Water Bodies

5.4 Alameda Creek Watershed Streams and Reservoirs

5.5 San Francisco Peninsula Streams and Reservoirs

5.6 Westside Basin Groundwater Resources

5.7 Cumulative Projects and Impacts Related to WSIP Water Supply and System Operations

(References included under each section)

5.1 Overview

5.1.1 Introduction

This chapter addresses the water supply and system operations aspects of the Water System Improvement Program (WSIP) and evaluates the potential environmental impacts of the proposed changes in water supply sources and regional water system operations. These impacts are generally distinct from the impacts associated with proposed construction and operation of the WSIP facility improvement projects described in Chapter 4, although there are some areas of overlap, which are described where appropriate. Together, Chapters 4 and 5 of this Program Environmental Impact Report (PEIR) present the impacts associated with implementation of the San Francisco Public Utilities Commission's (SFPUC) proposed program.

The impact discussions in Chapter 5 are organized by watershed and related drainages and reservoirs, rather than by environmental resource topics as in Chapter 4. This is because the water supply and system impacts are dependent on the local characteristics of each watershed and related resources. In this chapter, each watershed or water resource is discussed as a whole. There are three watershed areas of interest along the SFPUC's regional system: the Tuolumne River system, the Alameda Creek system, and the Peninsula system (including Pilarcitos Creek) (see **Figure 5.1-1**). In addition, the Westside Groundwater Basin is analyzed as a separate resource area only with respect to WSIP impacts on the groundwater resources, since the facilities-related

SFPUC Water System Improvement Program . 203287

Figure 5.1-1
Overview of Water Supply Watersheds
in the SFPUC Regional Water System

effects of construction and operation of the WSIP groundwater projects are evaluated in Chapter 4. Together, these watersheds and related water resources constitute the "program area" affected by the proposed water supply and system operations of the WSIP (Chapter 4, Section 4.1 defines the "study area," which encompasses the areas affected by proposed WSIP facilities).

For each watershed and related drainage area, this chapter addresses impacts on all environmental resources that could be affected by the proposed water supply option and system operations included in the proposed program: surface water hydrology, geomorphology, water quality, groundwater, fisheries and aquatic resources, riparian resources, recreational and visual resources, and, where applicable, water supplies and energy. Other resource topic areas analyzed in Chapter 4—land use, geology/soils/seismicity, cultural resources, traffic/transportation/ circulation, air quality, noise/vibration, public services and utilities, agricultural resources, and hazards—are not addressed in Chapter 5, since these resource areas would not be affected by changes in water supply and system operations (see Appendix B for more discussion).

Chapter 5 provides a *project-level* impact analysis of implementing: (1) the proposed WSIP water supply option to serve the projected 2030 average annual customer water purchase requests of 300 million gallons per day (mgd), and (2) the future regional system operations associated with meeting the WSIP's water supply and delivery reliability level of service objectives. Specifically, Chapter 5 provides a detailed analysis of the effects of increasing the average annual diversion from the Tuolumne River to serve customer purchase requests during both nondrought and drought periods through 2030. The project-level analysis evaluates the effects on the hydrology and related resources in the Tuolumne River, Alameda Creek, and Peninsula watersheds. Project-level mitigation measures have been identified, where appropriate, to address potentially significant impacts.

This detailed analysis is intended to fully address the effects of implementing the proposed WSIP water supply option through 2030 without the need for additional environmental review, with one exception. The exception that will require additional CEQA review is associated with the effects of the WSIP facility improvement project, Groundwater Projects (SF-2), on groundwater resources. The analyses in Sections 5.3 through 5.5 include the project-level impacts of taking additional water from the Tuolumne River to provide potable water from the regional system during nondrought years to serve those customers in San Mateo County that currently use groundwater from the Westside Basin; however, Chapter 5 does not evaluate the project-level impacts on the Westside Groundwater Basin of extracting the water from the basin during drought years. Section 5.6 analyzes the effects of the proposed conjunctive-use program and local groundwater projects on groundwater resources at a program-level, and subsequent project-level impact analysis of the proposed groundwater extraction activities on groundwater resources will be required, as appropriate, as specific well facilities are proposed under the WSIP facility improvement project for Groundwater Projects (SF-2).[1]

[1] Chapter 4 analyzes the program-level effects of implementing facilities needed for the Groundwater Projects (SF-2) and Recycled Water Projects (SF-3), and separate, project-level CEQA review on those facilities will be required. The project-level analysis of the proposed water supply option in Chapter 5 includes the effects of incorporating recycled water into systemwide operations.

5.1.2 Chapter Organization

Chapter 5 is organized as follows. Section 5.1 provides a description of the WSIP water supply option and system operations analyzed in this chapter as well as a general discussion of the approach to the analysis and rationale used in the impact evaluation for all watersheds. It describes the modeling tool used in the analysis and the chief assumptions made regarding system operations in the future. Specific differences in approach that are unique to each watershed are described in the individual sections. In addition, this overview section presents the definitions of significance determinations used throughout the chapter.

Section 5.2 presents a review of the plans, policies, and regulatory framework as they apply to relevant water supply issues as well as to watershed management of affected resources. In addition, the general regulatory framework for water and biological resources is included in this section, and specific details applicable to each watershed are provided in subsequent sections.

Section 5.3 covers the Tuolumne River drainage from Hetch Hetchy Reservoir to the river's confluence with the San Joaquin River and, as appropriate, also discusses the Delta.

Section 5.4 addresses the portion of the Alameda Creek watershed and major tributaries where it would be affected by the regional water system.

Section 5.5 encompasses drainage areas within the SFPUC Peninsula watershed, including the watersheds of San Mateo, Pilarcitos, and San Andreas Creeks and associated reservoirs.

Section 5.6 discusses the Westside Groundwater Basin resources that could be affected by the proposed WSIP groundwater projects, including both the local project in San Francisco as well as the regional projects proposed as part of the conjunctive-use program.

Section 5.7 presents an analysis of cumulative effects associated with the water supply sources and related resources. The section describes other past, present, and reasonably foreseeable future projects that could affect the same water resources and related environmental resources as the WSIP (as described in Sections 5.3 through 5.6) and evaluates the potential cumulative effects of implementing the WSIP in combination with those projects.

5.1.3 Proposed Water Supply Option and System Operations

This section reiterates the description of the proposed water supply option, as presented in Chapter 3.0, since it is the focus of the Chapter 5 impact analysis. The proposed water supply option addresses both the delivery reliability and water supply levels of service proposed under the WSIP, which are both associated with the projected increase in customer purchase requests (demand) through the year 2030. The proposed delivery reliability level of service is to increase the reliability of the regional system to serve average day customer demand of 300 mgd under a range of operating conditions, including providing for local reservoir replenishment and during planned maintenance, unplanned outages, and loss of water from any one water source. The proposed water supply levels of service are as follows: (1) to fully meet customer purchase

requests in nondrought years through the planning year 2030, estimated to be 300-mgd average annual delivery, and (2) to provide drought-year delivery with a maximum systemwide cutback of 20 percent in any one year of a drought.

Although no major changes are proposed under the WSIP with respect to regional system operations, there would be some operational refinements (described in Chapter 3, Section 3.7). The proposed facility improvements would upgrade and in some cases expand the system, allowing changes in operations that provide increased flexibility as well as increased delivery reliability. In particular, local Bay Area reservoirs would be maintained at higher water levels for longer periods of time under the WSIP than under the existing condition. By keeping water stored in local reservoirs, geographically close to the customers' demand, the SFPUC would be able to respond to service needs during a drought or other emergency, such as an unplanned facility outage.

Proposed Nondrought-Year Water Supplies

During nondrought conditions, the SFPUC proposes to serve the increased 35 mgd in average annual purchase requests through a combination of conservation, water recycling, and groundwater supply programs in San Francisco supplemented with increased diversions from the Tuolumne River. Under the proposed water supply option, the SFPUC would implement conservation, water recycling, and groundwater supply programs in the SFPUC retail service area to achieve the equivalent of 10 mgd of supply in all years (drought and nondrought).

The SFPUC proposes to serve the increase in customer purchase requests that are not served by conservation, water recycling, and groundwater supply programs through increased use of Tuolumne River water under its existing water rights and additional management of the local watershed resources with the restoration of the storage capacity of Calaveras and Crystal Springs Reservoirs. The regional system would continue to maximize its use of local watershed water supplies. This increased diversions from the Tuolumne River include additional diversions needed to serve 2030 purchase requests as well as maintaining local storage for supply reliability and implementation of Westside Basin conjunctive-use program.

Proposed Drought-Year Water Supplies

During drought years under the WSIP, the SFPUC would continue to use the nondrought-year water supplies described above and would make use of the following additional resources and measures to meet the 2030 needs:

- *Water transfers*. Obtain up to an equivalent of 23 mgd of supplemental Tuolumne River water through water transfer agreements with TID and MID such that water would be available for diversion in drought years.

- *Groundwater conjunctive-use program in the Westside Basin, San Mateo County*. Utilize the extraction component of a groundwater conjunctive-use program in the Westside Groundwater Basin in northern San Mateo County to provide the equivalent of approximately 6 mgd of water during prolonged drought to groundwater pumpers. This

includes providing potable water to groundwater pumpers and in-lieu groundwater recharge during nondrought years in return for reduced groundwater pumping during drought years.

- *Restoration of Calaveras and Crystal Springs Reservoir capacities*. Restore the historical operating storage capacities at Calaveras Reservoir to provide an equivalent of 7 mgd of additional water supply and at Crystal Springs Reservoir to provide an equivalent of 1 mgd of additional supply.

- *Rationing*. Implement up to 20 percent systemwide rationing if necessary in combination with use of the above supplemental water supplies.

To ensure that the water supplies would be available by 2030, the SFPUC is currently in the planning phase of the design and construction of needed facilities and is pursuing required agreements with other agencies. The SFPUC would secure these water supplies in phases as required to meet the increased customer demand between now and 2030, as reflected in **Figure 5.1-2**. Figure 5.1-2 shows the average annual historical customer deliveries as well as the projected future average annual demand. The figure indicates that between 2005 and 2030, the total customer purchase requests are estimated to increase by 35 mgd (annual average), from an annual average of 265 mgd to an annual average of 300 mgd. Retail customer demand would increase by about 1 mgd,[2] and the remaining increase would be from wholesale customers (see also Chapter 3, Table 3.4). Half of this increased demand is expected to occur before 2020, and the remaining by 2030.

This chapter evaluates the effects of implementing this proposed combination of actions and supplemental supplies to meet water supply and delivery needs and performance objectives through 2030.

Annual Average Historical and
Projected Future Customer Purchase Requests

2 The SFPUC retail service area high-range purchase estimate of 91 mgd assumes that San Francisco groundwater supply would be part of the regional water system supply.

5.1.4 Approach to the Analysis

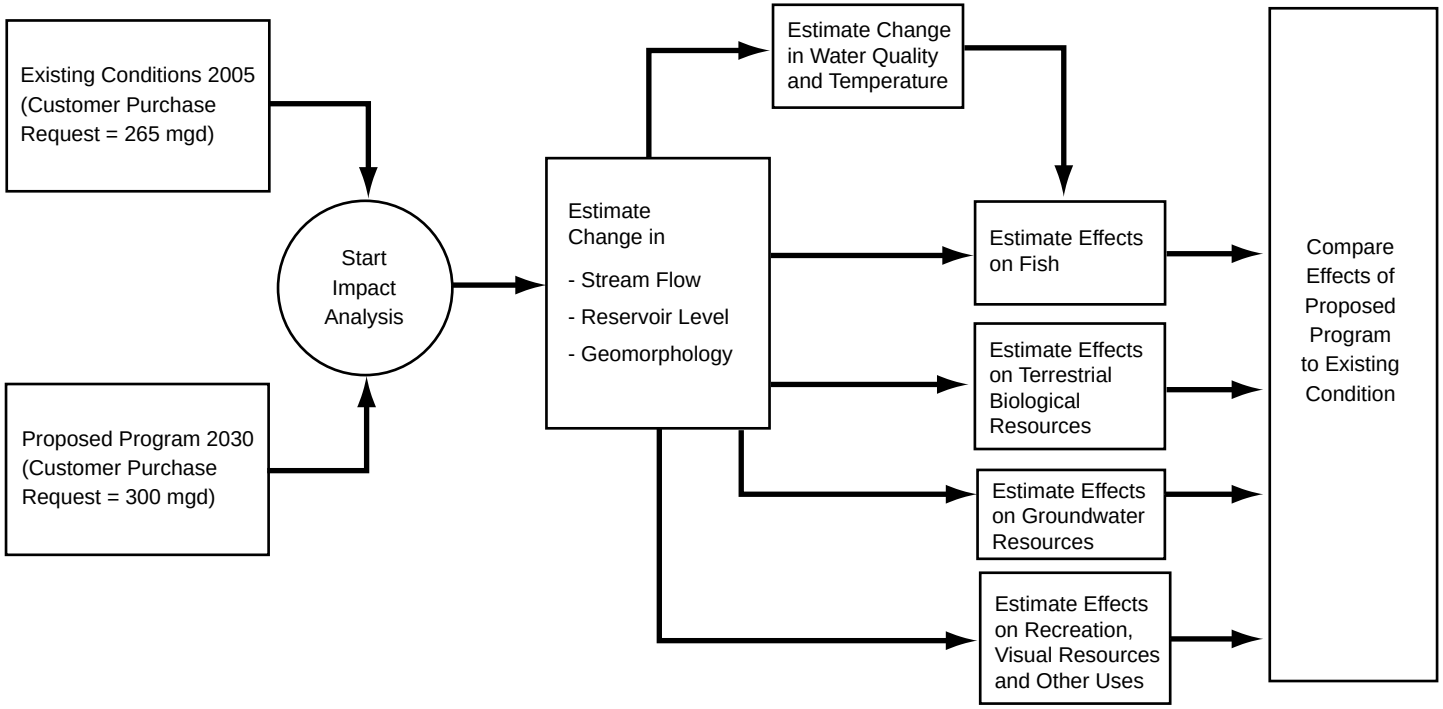
As part of WSIP implementation, additional water would be diverted from the Tuolumne River above the current average annual diversion levels in order to serve customer water delivery requirements and the other level of service goals established for the regional system through 2030. The analyses presented in Sections 5.3, 5.4, and 5.5 focus on the effects of this additional water diversion and of the related system operations needed to store and move that water from the Tuolumne River through the regional system of reservoirs and conveyance facilities to customers in the Bay Area. The analysis considers future system operations following implementation of all proposed WSIP projects in order to determine the effects that any adjustments in operations might have on the hydrology and related environmental resources in the three affected watersheds—the Tuolumne River, Alameda Creek, and Peninsula watersheds.

Relationship of Affected Resources

The basic approach to determining the potential impacts on water and related resources was the same for the three affected watersheds. First, changes in flow in the rivers and/or creeks and changes in water levels in each of the reservoirs were evaluated. These are the primary physical environmental changes that could occur with implementation of the water supply component of the WSIP, and these changes provide the basis for evaluating the potential related effects on other environmental resources. **Figure 5.1-3** depicts the interrelationships between, and among, changes in stream flow and reservoir storage levels and the potentially affected environmental resources.

Changes in stream flow under to the WSIP, which would primarily result from changes in the timing and quantity of water released from system reservoirs, were used to assess changes in the geomorphic processes for local streams (i.e., the sediment transport and channel-forming properties that define the nature of a stream course and its associated habitats). Stream flow and reservoir water level changes were then used to estimate changes in water quality. The chief water quality parameters that could be affected by changes in stream flow and reservoir levels are temperature and dissolved oxygen, and these parameters are the focus of the water quality analysis. The combination of changes in flow, reservoir levels, and water quality was then used to determine potential impacts on fisheries resources. Changes in flow and reservoir levels were also used to identify potential impacts on riparian habitat and related terrestrial biological resources. Finally, changes in flow and reservoir levels were used to identify potential impacts on water-related recreation, including whitewater rafting, boating, and fishing, and water-related visual resources. For the Tuolumne River watershed, the changes in flow and reservoir levels were also used to identify potential effects on downstream users and on energy supplies due to potential changes in hydropower generation.

The SFPUC operates and manages the regional water system (including the Tuolumne River system, the Alameda Creek system, and the Peninsula watershed system) in accordance with a complex and dynamic set of operational procedures that respond to changing climatic and hydrologic conditions, legal and regulatory requirements, water supply demands, and needs for maintenance, repair, and replacement of system facilities. In order to assess the changes to these systems that could occur under the WSIP, it was necessary to employ a computer modeling tool



SOURCE: ESA + Orion

Figure 5.1-3
Approach to Impact Analysis on Water Resources

with the capability of addressing the many factors involved in system operations and management and thus enabling a comparison of the "before" and "after" program conditions. The modeling tool and approach used for analysis are described in the following section.

Hetch Hetchy/Local Simulation Model

The amount of water available to the SFPUC varies from year-to-year depending on meteorological conditions, water rights, and statutory and contractual obligations, including the Raker Act. The SFPUC operates its water system to meet customer water demand as fully and efficiently as it can, despite the fact that the amount of water available to it varies from year-to-year. The operations of the water system are complex, involving numerous reservoirs, pipelines, and pumping plants. The SFPUC utilizes a computerized mathematical model to assist in the evaluation of its water systems operations—the Hetch Hetchy/Local Simulation Model (HH/LSM), a water supply planning model (SFPUC, 2007a). This model is the best available tool for depicting the overall regional water system operations under a range of conditions and is similar to the models used by other water purveyors in the United States to depict their water system operations and to plan for system improvements.

A general overview of this modeling tool and the basic assumptions about the system included in the model are described in this section. **Appendix H1** provides a more detailed description of the model and how it was used for the PEIR water supply and system operations impact analysis; **Appendix H2** provides supporting details and an explanation of raw data output from the model.

Representation of the Regional System in the Model

The HH/LSM incorporates detailed information about key aspects of the SFPUC regional water system, including facilities (i.e., reservoir and conveyance capacities) and operating procedures and "rules" that determine how and when water is moved through the system to customers. The operating procedures include responses to seasonal variation in demand, allocation of demand to customer groups, and procedures to maximize the use of local watershed supplies, while the rules include responses to regulatory requirements for instream flows and compliance with Raker Act obligations. As described in Chapters 2 and 3, water system operations can be generally delineated between rules and strategies affecting the operation of the Bay Area water system and rules and strategies affecting the operation of the Hetch Hetchy system. Although generally discussed separately, the two systems are integrally linked and are interdependent on each other in order to maximize water availability and quality.

For the Hetch Hetchy system, the HH/LSM integrates operations at SFPUC's three major reservoirs in the Tuolumne River watershed—Hetch Hetchy Reservoir, Lake Lloyd, and Lake Eleanor—with the operation of TID/MID's Don Pedro Reservoir, due to the SFPUC's water bank account in Don Pedro Reservoir (described in Chapter 2, Section 2.5.2). The operation of these reservoirs and the water bank account is guided by two primary objectives: (1) to conserve reservoir storage so as to optimize supply to SFPUC customers, and (2) to fulfill San Francisco's Raker Act obligation to bypass Tuolumne River flow to TID and MID. Underlying the operations at the SFPUC's reservoirs are the minimum fishery release requirements prescribed for Hetch

Hetchy Reservoir, Lake Lloyd, and Lake Eleanor. Water that is released from San Francisco's reservoirs and not diverted to SFPUC customers, together with runoff that originates below San Francisco's reservoirs, flows to Don Pedro Reservoir. The HH/LSM simulates TID/MID's operation of Don Pedro Reservoir, including simulation of canal diversions, flood control operations, and releases to meet fishery release requirements below La Grange Dam. The model also simulates the accounting for the SFPUC's water bank account.

The model uses a watershed runoff forecasting routine (for snowmelt and rainfall) that projects the amount of runoff that can be expected to flow into each reservoir for a particular time period. Once the amount of runoff is projected, this amount is compared to the availability of reservoir storage and the anticipated releases required from the reservoir to meet downstream flow requirements and the diversions needed for water deliveries to SFPUC customers. If a reservoir is projected to spill, the model incorporates discretionary releases that the SFPUC manages to enhance hydropower generation. The model uses a monthly time step. This forecasting and decision process occurs sequentially each month of the period being modeled.

For the local Bay area system, the model depicts the regional system as a linked series of inflows, reservoirs, conveyance routes, and areas of water demand. Numerous operational constraints are incorporated, including considerations for downstream channel conveyance capacity, treatment plant capacity, and water transmission capacity. The Bay Area system is operated to maximize the efficient use of local Bay Area watershed runoff and supplemented with Tuolumne River water resources. The model establishes optimal storage levels for each Bay Area reservoir by season; this relates to how the SFPUC manages reservoir storage levels to lower reservoir storage space prior to the rainy season and then to raise the level through the dry season. In San Antonio, Crystal Springs, and San Andreas Reservoirs, the model assumes that reservoir space is filled first with Bay Area watershed runoff and then supplemented with Tuolumne River water by late spring in order to ensure maximum local reservoir storage through the summer season.

Simulation of System Operations

Simulation Period

The model simulates system operations over the course of an 82-year sequential hydrologic period from July 1920 through September 2002. The model includes actual, measured historical information about the hydrology (the amount of runoff estimated from either snowmelt and/or rainfall) that occurred in each year over the 82-year record for each of the three watershed areas under consideration: the Tuolumne River system, the Alameda Creek system, and the Peninsula watershed system. This 82-year period includes many different types and sequences of actual hydrological events, ranging from flood events to droughts of different magnitude and duration. Because natural surface water systems are dynamic and runoff and flow vary each year, and as it is not possible to predict future precipitation, it is a necessary and standard industry practice to use a long-term historical record to represent the range of hydrologic conditions that can be expected in the future. The long-term 82-year historical record is used in the model to represent

the range of hydrologic conditions that could occur in the future[3] and to assess both how the system would perform in terms of meeting the WSIP level of service objectives and what types of impacts the program might have under a range of conditions.

The modeling tool uses information on actual historical hydrology but does not "predict" or necessarily precisely depict the past, historical operation of the system. The historical operation of the system in an actual year will differ from the operations simulated by the model for that year as a result of day-to-day adjustments made by the system operators, who constantly modify operations throughout the year to respond to changing conditions related to weather, demand, water quality, or facilities conditions (e.g., maintenance or unplanned facilities outages). While many of these factors are built into the model, the model cannot account for all the actual operations and adjustments made throughout each year. The objective of using the modeling tool is to assess the effect of system changes on future operations over a broad range of realistic hydrologic conditions.

Hydrologic Year Definitions

As described in detail in Appendix H1, all years in the 82 years of historical hydrology were ranked and grouped into hydrologic year types according to river and creek flow. Five hydrologic categories were used to depict the range of wet to dry years, depending on the hydrologic index. The hydrologic year types are defined differently for different watershed and drainage areas affected by the WSIP (referred to as the hydrologic index) in order to accurately reflect each area's unique hydrology. A hydrologic year is from October to September.

Hydrologic year types for the Tuolumne River above Don Pedro Reservoir are classified based on the SFPUC's calculation of unimpaired flow[4] for the Tuolumne River at La Grange. The 20 percent of years when unimpaired inflow to Don Pedro Reservoir was lowest were designated as dry years; the next driest 20 percent of years were designated as below-normal years, and so on. This index uses the following year types: wet, above normal, normal, below normal, and dry.

Hydrologic year types for the Tuolumne River below La Grange Dam are classified according to the California Department of Water Resources' San Joaquin River Index, which defines the following categories: wet, above normal, below normal, dry, and critically dry. This index was used to analyze Don Pedro Reservoir operations because release requirements from Don Pedro Reservoir at La Grange Dam are tied to this index.

Hydrologic year types for the Alameda Creek and Peninsula watersheds are also classified by the 20 percent grouping technique and are based on the SFPUC's estimation of local inflow into its five San Francisco Bay Area reservoirs. Annual flow into each of the reservoirs was summed for each water year. The 20 percent of years when total runoff into the five reservoirs was lowest were designated dry years. The next driest 20 percent of years were designated below-normal

[3] The potential effect of climate change on the SFPUC's regional system is addressed in Section 5.7 under Cumulative Impacts.

[4] The natural river flow that existed prior to the placement of upstream water diversions, storage reservoirs, or other impediments.

years, and so on. This index uses the following year types: wet, above normal, normal, below normal, and dry.

Model Assumptions and Output

The model evaluates system operations, performance, and effects on reservoir storage and reservoir releases (i.e., streamflow below the dam) under a given set of operating parameters utilizing the 82 years of historical hydrology. A differing set of operational objectives and/or a change in the physical configuration of the water system could result in different operations, system performance, and effects on reservoir storage and releases. The model is used to compare alternative operational objectives and system configurations. For the impact analysis presented in this chapter, the model was employed to simulate operations and the effects of those operations under an existing conditions scenario (2005) and under a WSIP scenario (2030).

Model Assumptions and Inputs

The model uses input information on key aspects of the regional water system, including the level of annual water delivery provided by the system, the maximum rationing to be allowed during a drought, and the state of the facilities (e.g., reservoir and conveyance capacities and configurations). **Table 5.1-1** summarizes the differences in key assumptions between the existing conditions and WSIP scenarios that were incorporated into the model and used in the CEQA impact analysis.

TABLE 5.1-1
MODELING ASSUMPTIONS USED IN THE CEQA ANALYSIS

Parameter	Existing Conditions Scenario	WSIP Scenario
Planning year	2005	2030
Customer purchase requests (average annual delivery) (mgd)	265 mgd	300 mgd
Average annual demand from regional system water supply sources (Tuolumne River and local watersheds)	265 mgd	290 mgd
Average annual delivery from other sources (recycled water, groundwater, conservation)	See note a	10 mgd[b]
System firm yield[c]	219 mgd	256 mgd
Maximum systemwide rationing during a drought	No policy cap – up to 25%	20%
WSIP facility improvement projects	None	All WSIP projects

[a] San Francisco and many of its retail and wholesale customers currently utilize recycled water, groundwater, and/or conservation practices to some extent, which is reflected in the 265 mgd average annual delivery.
[b] The 10 mgd reflects proposed implementation of recycled water, groundwater, and conservation projects in San Francisco to benefit the regional water system.
[c] System firm yield is defined as the average annual water delivery that can be sustained by the regional water system during an extended drought. The SFPUC uses an 8.5-year design drought for planning purposes. Due to the 2001 DSOD operational restrictions on Calaveras Dam, the system firm yield was 219 mgd as of September 2005, when the NOP for the PEIR was published. Normal system firm yield is 226 mgd, which reflects Calaveras Reservoir operating at its historical capacity.

The existing conditions scenario reflects the key information about the system for the year 2005, in accordance with CEQA guidance on the appropriate timeframe for determining the environmental baseline to be used for impact analysis.[5] The average annual water delivery from the regional system for the base year was 265 mgd. The existing conditions (2005) scenario reflects the regional system facilities as they were in 2005 (and remain today), including the restricted capacity at both Calaveras and Crystal Springs Reservoirs.

As described in Chapter 2, Section 2.2, the California Department of Water Resources, Division of Safety of Dams (DSOD) imposed operational restrictions on Calaveras Reservoir storage capacity in December 2001, which reduced the reservoir's normal capacity of 96,850 acre-feet to approximately 37,800 acre-feet. Prior to the DSOD restriction, Calaveras Reservoir had been operated at its full capacity for over 70 years (since completion of the Alameda Creek Diversion Dam and Tunnel in 1931). As a result of this restricted capacity, the SFPUC has had to significantly reduce its diversions through the Alameda Creek Diversion Dam compared to its 70 -year-long historical operations. The current capacity restriction will remain in effect—and thus the storage capacity will continue to be limited—until such time that the Calaveras Dam Replacement project (SV-2) is implemented. This project is scheduled for completion in 2012, at which time the restricted reservoir capacity will have been part of system operations for approximately 10 years. In order to present the most consistent baseline condition under CEQA, this PEIR uses an existing conditions scenario that reflects the current restriction on Calaveras Reservoir capacity, despite the fact that the reservoir had been operating at full capacity for 70 years. Implementation of the WSIP (specifically the Calaveras Dam Replacement project) would result in a change to these current operating conditions, restoring them in large part to conditions similar to the prior 70 years of operation. This PEIR examines the potential impacts of these changes.

The capacity of Crystal Springs Reservoir has been restricted since 1983 (also described in Chapter 2, Section 2.2.5); therefore, for this reservoir as well, an existing conditions scenario with restricted capacity is assumed, in compliance with CEQA.

As shown on Table 5.1-1, for the WSIP (2030) scenario, the model incorporates information about the expected average annual water delivery from the regional system in 2030, which under the WSIP is proposed to be 290 mgd. The other 10 mgd of supply needed to serve the total 2030 average annual customer purchase requests of 300 mgd is proposed to come from a combination of recycled water, groundwater, and conservation projects in San Francisco, to be implemented as part of the WSIP. The WSIP (2030) scenario also assumes that all proposed facility improvement projects have been fully implemented. This scenario thus includes the restoration of full storage capacity at Calaveras Reservoir and Crystal Springs Reservoir.

[5] CEQA Guidelines Section 15125(a) states that an EIR must include a description of the physical environmental conditions in the vicinity of the project, as they exist at the time the notice of preparation (NOP) is published, and that this environmental setting will normally constitute the baseline physical conditions against which the lead agency determines whether an impact is significant. The NOP for the WSIP PEIR was published in September 2005.

In addition to the input assumptions shown in Table 5.1-1, the model includes, for both the existing condition and WSIP scenarios, the same assumptions and rules for compliance with statutory and contractual obligations, including the Raker Act and minimum instream flow requirements.

Model Outputs

Once the operation of the regional water system was modeled under each scenario, the model provided output information about system performance under that scenario in terms of the WSIP system objectives and about the timing and amount of water in reservoir storage and released from the system reservoirs downstream. In general, the model provides information on a monthly basis. **Table 5.1-2** summarizes key output information provided by the model.

During actual system operations, operators make decisions about how much water to retain in storage and how much water to release from system reservoirs on an hourly, daily, or weekly basis in response to changing conditions. The model does not report these changes at this level of detail. Like other computer models used elsewhere in California to predict the impacts of proposed projects on complex water storage and delivery systems (e.g., the Central Valley Project and State Water Project), the HH/LSM identifies monthly levels in various storage facilities and water bodies, and does not have the necessary precision to deal with hourly, daily, or weekly operational decisions. The state of the art in modeling has not yet reached the point where such precision is possible. In most cases, however, the monthly information about changes in reservoir storage and reservoir releases downstream was adequate for the purpose of assessing the nature, magnitude, and frequency of potential physical changes and environmental impacts associated with operations under the proposed WSIP program scenario compared to the existing condition. In those cases where more detailed information is needed for impact analysis than is available from monthly data, the SFPUC system operators were consulted about daily or weekly operations and, where available, historical data on the system operation were reviewed. Thus, in these instances, the conclusions set forth in the PEIR reflect not only the results of the HH/LSM, but also input from the experienced system operators regarding how they would likely respond to the kinds of issues that might arise on a daily a weekly basis.

Model Limitations

The HH/LSM is the best available tool for depicting changes in the overall regional water system operations; however, as explained above and further explained here, in some cases, limitations inherent in the model required that the analysis be supplemented by additional data.

For example, the HH/LSM was used to estimate baseline and with-WSIP water levels in all SFPUC reservoirs except for Pilarcitos Reservoir. Model results for the Pilarcitos watershed were not directly used to analyze existing and projected water levels in Pilarcitos Reservoir or flows in Pilarcitos Creek. The model does not currently reflect a complete contemporary depiction of the physical operation of the Pilarcitos watershed's facilities. Although adequate for SFPUC's systemwide water supply planning purposes, HH/LSM results for the Pilarcitos watershed at times required supplemental refinement and analysis to accurately reflect the physical infrastructure in place in the watershed.

TABLE 5.1-2
HH/LSM OUTPUT PARAMETERS
(Data provided as monthly time step for 82 years of historical hydrology)

Feature	Output Parameter
TUOLUMNE RIVER SYSTEM	
Unimpaired Inflow (acre-feet)	Inflow to Hetch Hetchy Reservoir
	Inflow to Lake Lloyd
	Inflow to Lake Eleanor
	Unregulated Flow below Hetch Hetchy Reservoir
End-of-Month Storage (acre-feet)	Hetch Hetchy Reservoir Storage
	Lake Lloyd Storage
	Lake Eleanor Storage

	Calaveras Reservoir Release to Calaveras Creek
	Calaveras Reservoir Spill to Calaveras Creek
	Calaveras Reservoir Evaporation

TABLE 5.1.2 (Continued)
HH/LSM OUTPUT PARAMETERS
(Data provided as monthly time step for 82 years of historical hydrology)

Feature	Output Parameter
San Antonio (MG)	San Antonio Reservoir Storage
	San Antonio Reservoir Inflow from San Antonio Creek
	San Antonio Reservoir Inflow from Calaveras Reservoir/SJPL
	San Antonio Reservoir Release to Sunol Valley WTP
	San Antonio Reservoir Release to San Antonio Creek
	San Antonio Reservoir Evaporation
Crystal Springs (MG)	Crystal Springs Reservoir Storage
	Crystal Springs Reservoir Inflow from San Mateo Creek
	Crystal Springs Reservoir Inflow from San Andreas Reservoir
	Crystal Springs Reservoir Inflow from Bay Division Pipelines
	Crystal Springs Reservoir Pumping to San Andreas Reservoir
	Crystal Springs Reservoir Pumping to Coastside CWD
	Crystal Springs Reservoir Release to San Mateo Creek
	Crystal Springs Reservoir Spill to San Mateo Creek
	Crystal Springs Reservoir Evaporation
San Andreas (MG)	San Andreas Reservoir Storage
	San Andreas Reservoir Inflow from Watershed
	San Andreas Reservoir Inflow from Crystal Springs, San Mateo Creek & Pilarcitos
	San Andreas Reservoir Release to Harry Tracy WTP
	San Andreas Reservoir Release to San Mateo Creek
	San Andreas Reservoir Spill to San Mateo Creek
	San Andreas Reservoir Evaporation
Pilarcitos (MG)	Pilarcitos Reservoir Storage
	Pilarcitos Reservoir Inflow
	Pilarcitos Reservoir Release to San Andreas Reservoir
	Pilarcitos Reservoir Release for Stone Dam Diversion to Coastside CWD
	Pilarcitos Reservoir Pre-Release to Pilarcitos Creek
	Pilarcitos Reservoir Spill to Pilarcitos Creek
	Pilarcitos Reservoir Evaporation
Stone Dam (MG)	Stone Dam Inflow (Accretion)
	Stone Dam Release to Coastside CWD
	Stone Dam Release to Crystal Springs Reservoir
Reservoir Storage (MG)	Total Reservoir Storage – East Bay
	Total Reservoir Storage – Peninsula
	Total Local Storage
	Maximum Targeted Total Local Storage
Demand (MGD)	Delivery to South Bay Demand Center
	Delivery to Crystal Springs Demand Center
	Delivery to San Andreas Demand Center
	Delivery to In-City Demand Center
	Total Delivery to Demand Centers (not including Coastside CWD)
Demand (MG)	Delivery to South Bay Demand Center
	Delivery to Crystal Springs Demand Center
	Delivery to San Andreas Demand Center
	Delivery to In-City Demand Center
	Total Delivery to Demand Centers (not including Coastside CWD)
San Joaquin Pipelines	SJPL Flow – MG
	SJPL Flow – MGD
SJPL (MG)	SJPL Flow to Crystal Springs Reservoir – MG
	SJPL Flow to San Antonio Reservoir – MG
West Basin Reservoir (MG)	Beginning of Month Storage
	West Basin Reservoir – Input Resulting from San Andreas Gradient Deliveries
	West Basin Reservoir – Input Resulting from Crystal Springs Gradient Deliveries
	End of Month Storage
Desalination Project (MG)	Input from Desalination Project
Treatment Plant Delivery (MGD)	Calaveras Reservoir Flow to Sunol Valley WTP
	San Antonio Reservoir Flow to Sunol Valley WTP
	Sunol Valley WTP Production
	Harry Tracy WTP Production

Indicates data used in the PEIR analysis

Coastside CWD = Coastside County Water District; MG = million gallons; MGD = million gallons per day; MWh = megawatt-hours; MID = Modesto Irrigation District; SJPL = San Joaquin Pipelines; TID = Turlock Irrigation District; WTP = water treatment plant.

The HH/LSM was also used to estimate baseline and with-WSIP flows in the Tuolumne River and Alameda Creek. However, the model results were not solely relied upon when evaluating flows in creeks immediately downstream of SFPUC reservoirs that normally have minimal flow or are affected by SFPUC operations for time periods less than a month in duration. This is because the model uses a monthly time interval. The model does not simulate day-to-day variations in water levels or releases to a stream, but instead provides an average water level and an average release in a given month. The inability of the model to illustrate short-term variations is generally not problematic when simulating continuous phenomena like storage or water level in a reservoir or flow in a perennial stream. However, in some cases, the modeling limitation of only providing information at a monthly time interval required additional considerations, such as SFPUC operator experience and knowledge, when simulating intermittent phenomena such as infrequent spills or releases from reservoirs that may last only a few days.

Flow in San Mateo Creek downstream of Lower Crystal Springs Dam provides an example. The SFPUC system operators rarely release water from Crystal Springs Reservoir to San Mateo Creek, and flow in the creek below the dam typically occurs only from seepage from the dam and groundwater infiltration. The SFPUC operators attempt to capture and retain as much runoff as possible from the upper San Mateo Creek watershed in Crystal Springs Reservoir. In all but wet years, the SFPUC captures all of the runoff from the upper watershed. In wet months of wet years, the operators of the reservoir obtain frequent weather forecasts and manage the reservoir to capture as much runoff as possible from the sequence of winter storms that cross the watershed. The operator's decisions with respect to reservoir management are made on a day-to-day, sometimes hour-to-hour, basis. In certain circumstances during wet hydrologic conditions, the operators must release water from the reservoir to the creek due to unpredictable weather conditions and their limited ability to make further adjustments to reservoir levels and other systemwide operations. Releases from Crystal Springs Reservoir to San Mateo Creek are based on day-to-day changes in operations and thus cannot be modeled using the HH/LSM. Consequently, the model does not provide a refined prediction of the magnitude and timing of infrequent and short-term releases from the reservoir. Similarly, the model does not provide a precise prediction of the magnitude and timing of releases from San Antonio Reservoir and flow in San Antonio Creek downstream of the reservoir. However, HH/LSM results are sufficient to depict the general trends of WSIP effects on these parameters on a monthly basis.

For the reasons noted above, HH/LSM results were not used to predict water levels in Pilarcitos Reservoir, flows in Pilarcitos Creek, or the magnitude and timing of spills or releases from Crystal Springs and San Antonio Reservoirs. In these cases, the likely effects of the WSIP were determined through a review of historical data and consultation with individuals knowledgeable about the past and predicted future reservoir operating practices.

In additional instances, such as the analyses of flow effects below Hetch Hetchy Reservoir and below the Alameda Creek Diversion Dam, HH/LSM results were refined or tiered to provide additional insight into the effects of the WSIP on stream flow for time periods of less than a month.

Use of Model Results to Show Water Supply Sources

Figures 5.1-4 and **5.1-5** present model results showing the relative contributions of the various water supply sources to the regional system for the 82-year period of hydrologic record under existing conditions (2005) and WSIP conditions (2030), respectively. The figures illustrate the combination of supply sources the regional system would use year-to-year to serve customer deliveries if it were operated over a series of years similar in terms of climate conditions to those that occurred from 1920 to 2002 under the two scenarios. The figures depict how relative contributions of water supply sources available to the SFPUC would vary from year to year and show the frequency and extent of shortages and rationing that would occur if there were dry years and drought sequences similar to those that occurred during this period.

The figures indicate that there currently is, and would continue to be, a wide annual variation in the amount of water available from the various water sources under both current and future conditions. This, in turn, results in a wide variation in the changes in stream flow and reservoir water levels that would occur under the WSIP compared to the existing condition. Therefore, the impact analysis presented in this chapter addresses the effects of this range of variation in stream flow and reservoir level changes on the potentially affected watersheds and associated resources.

5.1.5 Impact Significance Determinations

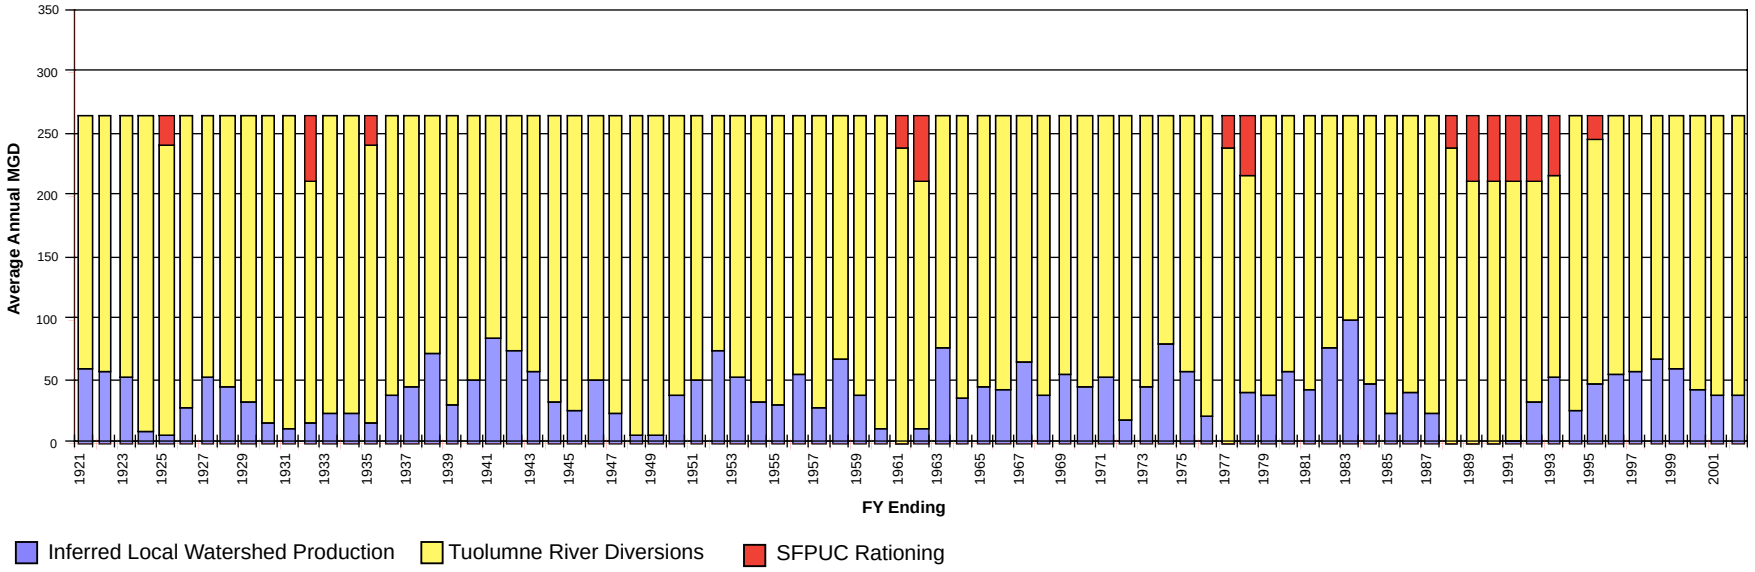
The significance criteria used in this PEIR are based on San Francisco Planning Department, Major Environmental Analysis (MEA) guidance regarding the environmental effects to be considered significant. MEA guidance is, in turn, based on the CEQA Guidelines Appendix G with some modifications. In cases where potential environmental issues associated with the WSIP are identified but are not clearly addressed by MEA's guidance, additional impact significance criteria are presented. Appendix B of this PEIR presents the MEA Initial Study checklist as it applies to the WSIP, and indicates the criteria applicable to the WSIP and discussed in the various chapters in the PEIR. The significance criteria used for each environmental topic/resource area are presented in each section of Chapter 5 following the setting and before the discussion of impacts.

For the impact analyses, the following categories are used to determine impact significance:

Not Applicable/No Impact (N/A). An impact is considered not applicable to the WSIP water supply or system operations if the environmental resource or impact potential does not occur within the project area or the area of potential effect. For example, an impact on a biological resource may not be applicable if the WSIP would not result in changes in stream flow for a specific reach of a creek.

Beneficial (B). An impact is considered beneficial if it is determined that WSIP water supply or system operations would improve an environmental resource or result in a beneficial effect on the environment.

Less than Significant (LS). This determination applies if there is a potential for limited impact, but the impact does not constitute a substantial adverse effect that qualifies under the significance criteria as a significant effect. LS impacts do not require mitigation.

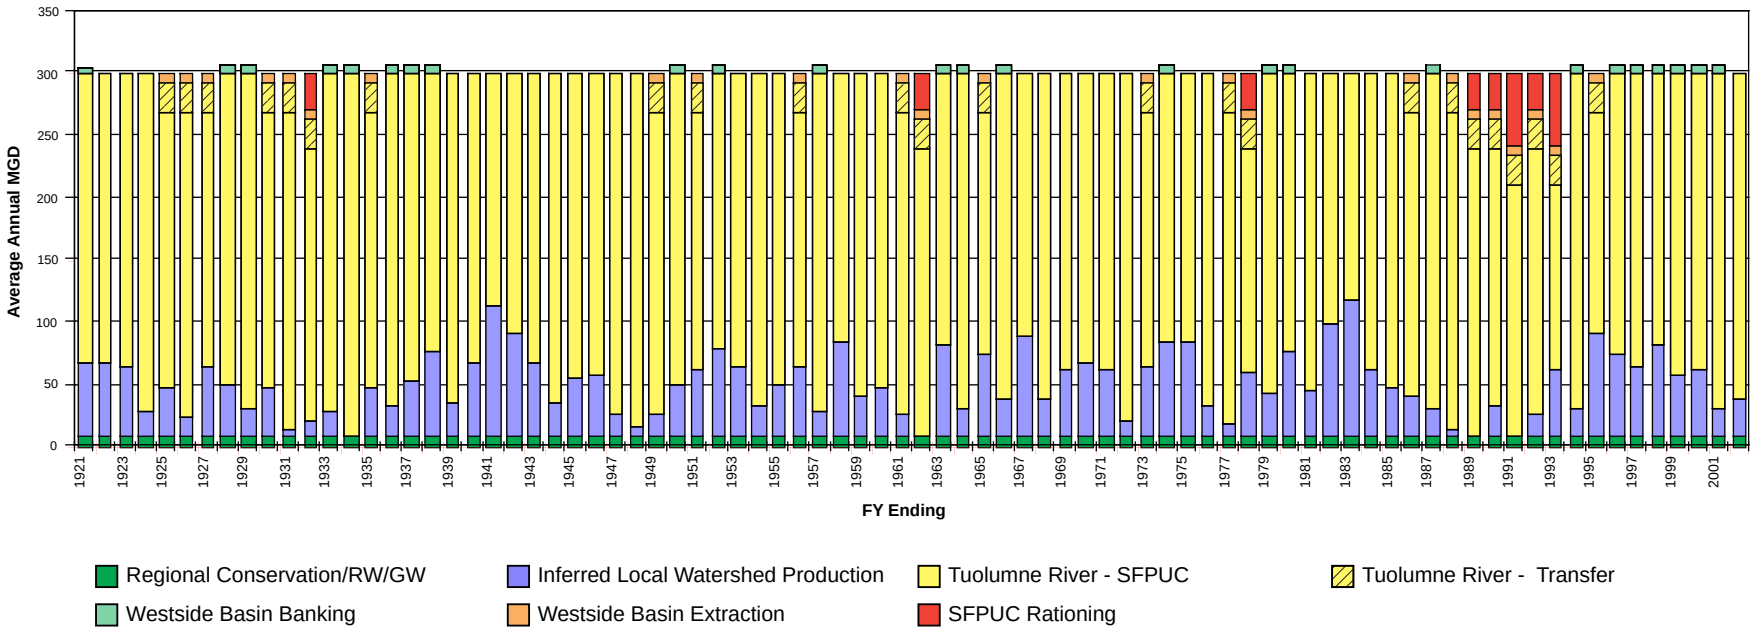


This figure illustrates what combination of supply sources the regional system would use year to year under existing conditions to meet the existing system delivery demand of 265 mgd if it were operated over a long series of years similar in terms of climate conditions to those that occurred between 1920 and 2002. This 82-year simulation illustrates how the relative contribution of water supply sources available to the SFPUC would vary year to year and shows the frequency and extent of supply shortages and rationing that would occur if there were dry years and drought periods similar to those that occurred during this historic period.

NOTES: (1) This figure illustrates a conceptual breakdown of water sources available to the SFPUC regional system. Local Watershed Production (inferred) is estimated as the difference between the amount of water delivered to system customers and the amount of water provided by the San Joaquin pipeline (Tuolumne River) and extracted from the Westside Basin groundwater aquifer. This estimate does not account for the source of Bay Area system reservoir storage used to serve deliveries or the partial use of San Joaquin pipeline deliveries for replenishment of Bay Area system reservoirs.

SOURCE: SFPUC, HH/LSM (see Appendix H)

Figure 5.1-4
Water Supply Sources and Shortages – Existing Conditions (265 mgd Delivery)



This figure illustrates what combination of supply sources the regional system would use year to year under future 2030 conditions to meet the future demand of 300 mgd if it were operated over a long series of years similar in terms of climate condition to those that occurred between 1920 and 2002. This 82-year simulation illustrates how the relative contribution of water supply sources available to the SFPUC would vary year to year and shows the frequency and extent of supply shortages and rationing that would occur if there were dry years and drought periods similar to those that occurred during this historic period.

NOTES: (1) This figure illustrates a conceptual breakdown of water sources available to the SFPUC regional system. Local Watershed Production (inferred) is estimated as the difference between the amount of water delivered to system customers and the amount of water provided by the San Joaquin pipeline (Tuolumne River) and extracted from the Westside Basin groundwater aquifer. This estimate does not account for the source of Bay Area system reservoir storage used to serve deliveries or the partial use of San Joaquin pipeline deliveries for replenishment of Bay Area system reservoirs.
(2) Deliveries in excess of 300 mgd represent banking of water into the Westside Basin groundwater aquifer under the proposed Westside Basin Groundwater conjunctive use program.

SOURCE: SFPUC, HH/LSM (see Appendix H)

Figure 5.1-5
Water Supply Sources and Shortages – 2030 WSIP Conditions (300 mgd Delivery)

Potentially Significant, Mitigable (PSM) / Significant Mitigable (SM). These determinations apply if there is a potential for a substantial adverse effect that meets the significance criteria, but implementation of mitigation measures would reduce the impact to a less-than-significant level. In cases where the analysis cannot conclusively determine the extent of adverse effects, the PEIR errs on the conservative side by identifying the impact as "potentially" significant; the impacts identified as "potentially significant" are treated as significant impacts in this PEIR. Similarly, "significant, mitigable" applies if there is certainty that a substantial adverse effect that meets the significance criteria would occur, but implementation of mitigation measures would reduce the impact to a less-than-significant level. In either event, the mitigation measures identified in this PEIR are expected to reduce any significant effects to a less-than-significant level.

Potentially Significant, Unavoidable (PSU) / Significant, Unavoidable (SU). These determinations apply to impacts that are potentially significant or significant, but for which there appears to be no feasible mitigation available to reduce them to a less-than-significant level. Mitigation might be available to lessen the effect of the impact, but the residual effect, even after implementation of the measure, would remain significant and therefore unavoidable. Alternatively, the PSU determination is applied in cases where mitigation might lessen the effect of an impact, but it is unknown if the mitigation could effectively reduce the impact to a less-than-significant level. When the effectiveness of a mitigation measure is unknown, the PEIR errs on the conservative side and applies this determination. The impacts identified as potentially significant are treated as significant impacts in this PEIR.

In each section of this chapter, a summary table is provided at the beginning of each impact discussion to summarize the potential impacts and to indicate the level of impact significance. The impact discussions for the WSIP water supply and system operations are organized by watershed or affected water resource. Impacts are numbered by section, and corresponding numbers are used to identify the mitigation measures presented in Chapter 6.

5.2 Plans and Policies

Section 5.2 Subsections	
5.2.1	Overview
5.2.2	Regulatory Framework
5.2.3	Relevant Plans, Policies, and Planning Action
5.2.4	Plan Consistency Evaluation
(References included under each section)	

5.2.1 Overview

The purpose of this section is two-fold: (1) to provide an overview of the federal, state, and local plans and policies governing the SFPUC's water supply, including water quality, water use, and natural resource protection; and (2) to describe program consistency with applicable, adopted land use and resource plans and policies relevant to the WSIP water supply option and system operations, pursuant to CEQA Guidelines Section 15125(d).

The regulatory overview for Chapter 5 is summarized in this section to avoid repetition of the general description of applicable environmental regulations in the various sections of this chapter. Because Chapter 5 is organized by watersheds and related drainage areas rather than by environmental resources, only those aspects of the regulations specifically applicable to each watershed are presented in the respective sections. For example, the regulatory overview for Chapter 5 presented in this section includes a general description of the Clean Water Act and the Porter-Cologne Water Quality Control Act, but the description of applicable water quality control plans (WQCPs), beneficial uses, and water quality objectives are described separately in Sections 5.3.3, 5.4.3, and 5.5.3 for the Tuolumne River, Alameda Creek, and Peninsula watersheds, respectively.

The analysis in this section complements that presented in Section 4.2, Plans and Policies, which focuses on land use plans and policies relevant to construction and operation of the proposed WSIP facility improvement projects. Together, Sections 4.2 and 5.2 provide an evaluation of project consistency with the overall plans and policies relevant to the proposed program.

5.2.2 Regulatory Framework

In general, implementation and enforcement responsibility of governmental regulations flows down from federal and state jurisdictions to the regional, county, and municipal levels. Although the federal government establishes programs and sets minimum standards that are applicable nationwide, state and local jurisdictions have the authority to set more stringent standards than those established under federal law. The SFPUC currently complies with all applicable federal, state, and local regulations regarding municipal water supplies and would continue to do so under the WSIP. Responsible agencies and applicable federal, state, and local statutes and agreements

are discussed below. **Table 5.2-1** summarizes the applicability of the statutes and agreements to the proposed WSIP water supply and system operations.

Federal Agencies

U.S. EPA Office of Water

The U.S. Environmental Protection Agency (U.S. EPA) Office of Water, established in 1970, is the primary federal agency responsible for implementation of the Clean Water Act and Safe Drinking Water Act. The U.S. EPA Office of Water provides guidance, specifies scientific methods and data collection requirements, establishes contaminant thresholds, and provides oversight to state and local governments for compliance with the Clean Water Act and Safe Drinking Water Act.

U.S. Army Corps of Engineers

The U.S. Army Corps of Engineers (Corps) evaluates permit applications for essentially all construction activities that occur in the nation's waters, including wetlands. Corps permits are also necessary for any work, including construction and dredging, in the nation's navigable waters. The Corps enforces the provisions of Section 404 of the Clean Water Act.

U.S. Fish and Wildlife Service

The mission of the U.S. Fish and Wildlife Service (USFWS) is to provide leadership in protecting fish and wildlife, conserving species habitats, and engaging citizens in the shared stewardship of America's natural resources. The USFWS's primary responsibilities involve the protection of migratory birds, endangered species, certain marine animals, and freshwater and anadromous fish through various regulations, including the Federal Endangered Species Act, the Federal Power Act, and Section 404 of the Clean Water Act.

National Marine Fisheries Service

The National Marine Fisheries Service (NMFS) is the primary federal agency involved with the stewardship of marine resources and their habitats through science-based conservation and management. The NMFS receives its ocean stewardship responsibilities under many federal laws, including the Federal Endangered Species Act, Section 404 of the Clean Water Act, and the Federal Power Act.

The Department of the Interior and the Department of Agriculture

The Department of the Interior (DOI) and the Department of Agriculture are the primary federal agencies involved with regulation under and enforcement of the Raker Act (see Chapter 2, Section 2.4.2, for further description of the Raker Act).

TABLE 5.2-1
APPLICABLE FEDERAL, STATE, AND LOCAL STATUTES AND AGREEMENTS

Statute or Agreement / Responsible Agency[a]	Summary Description	Associated Statutes and Plans	Applicability to WSIP Water Supply and System Operations Issues
Federal			
Clean Water Act / U.S. EPA, Corps, USFWS, NMFS	Primary federal law governing water quality. Prescribes basic federal laws for regulating discharges of pollutants into waters of the U.S., including establishing water quality standards for contaminants in surface waters, establishing wastewater and effluent discharge limits from various industry categories, and imposing requirements for controlling nonpoint-source pollution.	Section 303(d), Section 404, various others	Discussed and analyzed by watershed in Sections 5.3.3, 5.3.6, 5.4.3, 5.4.6, 5.5.3, and 5.5.6.
Safe Drinking Water Act / U.S. EPA	Sets health-based standards for drinking water quality to protect against naturally occurring and man-made contaminants that can be found in drinking water.	National Primary and Secondary Drinking Water Regulations	Described in Chapter 2, Section 2.4.1, regarding existing system, and in Chapter 3, Section 3.5.1, regarding proposed program.
Raker Act / U.S. Congress	Granted the City and County of San Francisco (CCSF) rights-of-way to certain public lands, including public lands in Yosemite National Park and Stanislaus National Forest, to develop water and power.		Described in Chapter 2, Section 2.4.2, and in Chapter 3, Sections 3.6 and 3.7, regarding existing and proposed water supply and operations.
Wilderness Act / U.S. Congress	Established the National Wilderness Preservation System to be composed of federally owned lands designated by Congress as wilderness areas, to be administered in such a manner that will leave them unimpaired for future use.	National Wilderness Preservation System	Designation of the 459-square-mile Tuolumne River watershed above Hetch Hetchy Reservoir as a wilderness area provides unique measures of protection to the watershed. Discussed in Section 5.2.3.
Wild and Scenic Rivers Act / BLM, NPS, USFS	Preserves the free-flowing characteristics and outstanding values of designated rivers while allowing uses compatible with the management goals of that river.	Management plans and concept plans for designated rivers	Described in Section 5.2.3 and evaluated in Section 5.2.4 for consistency. Discussed and analyzed in Section 5.3.7 regarding biological resources, as well as in Section 5.3.8 regarding visual resources.
Endangered Species Act / USFWS, NMFS	Provides broad protection for species of fish, wildlife, and plants that are listed as threatened or endangered in the U.S. or elsewhere.	Habitat conservation plans	Discussed by watershed in Sections 5.3, 5.4, and 5.5, under Fisheries and Terrestrial Biological Resources.
New Don Pedro Project FERC Settlement Agreement / FERC	Established a revised instream flow schedule for New Don Pedro Project operation and outlined a strategy for recovery of Tuolumne River Chinook salmon.	Habitat Restoration Plan for the Lower Tuolumne River Corridor (guidance document)	Discussed in Chapter 2, Section 2.5, under Institutional Considerations, in Chapter 3, Section 3.8, regarding proposed operations, and Sections 5.3.6, Fisheries, and 5.3.7, Biological Resources.

TABLE 5.2-1 (Continued)
APPLICABLE FEDERAL, STATE, AND LOCAL STATUTES AND AGREEMENTS

Statute or Agreement / Responsible Agency[a]	Summary Description	Associated Statutes and Plans	Applicability to WSIP Water Supply and System Operations Issues
State of California			
California Water Code / DWR and SWRCB	Contains the basic provisions regarding management of the state's water resources as well as the legislative findings for the California Water Plan.	California Water Plan, Water Reuse Law, California Recycling Act, Urban Water Management Planning Act, Wholesale Regional Water System Security and Reliability Act, etc.	Used in ongoing management and operation of the regional water system as well as in development of the WSIP.
California Water Code, Sections 10610–10656, Urban Water Management Planning Act / DWR	Requires urban water suppliers that provide water to 3,000 or more customers, or that provide over 3,000 acre-feet of water annually, to prepare an urban water management plan (UWMP) every five years.	UWMPs prepared by the CCSF and applicable Bay Area Water Supply and Conservation Agency (BAWSCA) members	Information in the UWMPs of the CCSF and BAWSCA members was used in the development of the WSIP 2030 level of service for water supply, as discussed in Chapter 3, Section 3.4.4, and Chapter 7; the San Francisco UWMP is analyzed in Section 5.2.
California Water Code, Sections 73500–73514, Wholesale Regional Water System Security and Reliability Act (AB 1823) / California legislature / DHS	Requires the SFPUC to operate the regional water system in a manner that will not adversely affect the water system. Includes the Water First Policy, which specifies that the CCSF shall assign higher priority to the delivery of water to the Bay Area than to the generation of electrical power.	WSIP (referred to as a capital improvement program in the legislation but renamed as the WSIP)	Part of WSIP development, goals, objectives, and operations, as described in Chapter 2, Section 2.4, and Chapter 3, Sections 3.4 and 3.7.
Porter-Cologne Water Quality Control Act / SWRCB, RWQCBs	Established SWRCB and RWQCBs as the principal state agencies with primary responsibility for the coordination and control of water quality. Established a comprehensive program for the protection of water quality and beneficial uses of water. Applies to surface waters (including wetlands), groundwater, and point and nonpoint sources of pollution.	Water quality control plans (WQCPs) designate legally binding beneficial uses of water for water bodies, including wetlands, assign water quality objectives (criteria) to protect those uses, and establish appropriate implementation programs.	Discussed and analyzed by watershed in Sections 5.3, 5.4, and 5.5, in the Surface Water Quality and Groundwater sections.
California Safe Drinking Water Act / DHS	Strengthens minimum requirements found in the federal Safe Drinking Water Act. Establishes drinking water standards that are at least as stringent as, and sometimes more stringent than, those established under the federal act.	Drinking water requirements, including Primary and Secondary Maximum Contaminant Levels	Discussed in Chapter 2, Section 2.4.1, and Chapter 3, Section 3.5.1, pertaining to WSIP water quality objectives.
San Joaquin River Agreement / SWRCB	Provides the basis for the development of the Vernalis Adaptive Management Program (VAMP) study and identifies where the water to support the VAMP study would be obtained.	Vernalis Adaptive Management Program (Experimental study)	Discussed in Sections 5.2 and 5.3.1.

TABLE 5.2-1 (Continued)
APPLICABLE FEDERAL, STATE, AND LOCAL STATUTES AND AGREEMENTS

Statute or Agreement / Responsible Agency[a]	Summary Description	Associated Statutes and Plans	Applicability to WSIP Water Supply and System Operations Issues
Regional and Local			
San Francisco City Charter / CCSF	Establishes many of the procedures and requirements for initiative ordinances and declarations of policy.	San Francisco General Plan San Francisco Sustainability Plan SFPUC Alameda Watershed Management Plan SFPUC Peninsula Watershed Management Plan SFPUC Stewardship Policy	Sets forth guidance and authority of the SFPUC for construction, management, supervision, maintenance, extension, expansion, and operation of the regional water system.

[a] Responsible agencies are as follows:

BLM = Bureau of Land Management
CCSF = City and County of San Francisco
Corps = U.S. Army Corps of Engineers
DHS = California Department of Health Services
DWR = California Department of Water Resources
FERC = Federal Energy Regulatory Commission
NMFS = National Marine Fisheries Service
NPS = National Park Service
RWQCB = Regional Water Quality Control Board
SFPUC = San Francisco Public Utilities Commission
SWRCB = State Water Resources Control Board
U.S. EPA = U.S Environmental Protection Agency
USFS = U.S. Forest Service
USFWS = U.S. Fish and Wildlife Service

Bureau of Land Management

The Bureau of Land Management (BLM), an agency within the U.S. Department of the Interior, administers America's public lands within a framework of numerous laws, including the federal Wild and Scenic Rivers Act. The BLM manages a wide variety of resources and uses, including fish and wildlife habitat, wilderness areas, timber, and archaeological, paleontological, and historical sites.

National Park Service

The National Park Service (NPS) is a bureau of the U.S. Department of the Interior. The NPS is responsible for the oversight of nearly 400 natural, cultural, and recreational sites across the nation, including scenic rivers and trails. The NPS is also responsible for the management of Yosemite National Park, administration of the designated wild and scenic reaches of the Tuolumne River under the Wild and Scenic Rivers Act, and preparation of the *Tuolumne Wild and Scenic River Comprehensive Management Plan* and the *Tuolumne Meadows Concept Plan* (both in development).

Federal Statutes and Agreements

Clean Water Act

The Clean Water Act, enacted by Congress in 1972 and amended several times since inception, is the primary federal law regulating water quality in the U.S. and forms the basis for several state and local laws throughout the country. Its objective is to reduce or eliminate water pollution in the nation's rivers, streams, lakes, and coastal waters. The Clean Water Act prescribes the basic federal laws for regulating discharges of pollutants into waters of the U.S., including setting water quality standards for contaminants in surface waters, establishing wastewater and effluent discharge limits from various industry categories, and imposing requirements for controlling nonpoint-source pollution. At the federal level, the Clean Water Act is administered by the U.S. EPA. At the state and regional levels, the act is administered and enforced by the State Water Resources Control Board (SWRCB) and the Regional Water Quality Control Boards (RWQCBs).

Section 404 of the Clean Water Act established a program to regulate the discharge of dredged or fill material into waters of the U.S., including wetlands. Activities in waters of the U.S. regulated under this program include the placement of fill for development, water resource, infrastructure, and mining projects. Section 404 requires a permit before dredged or fill material may be discharged into waters of the U.S., unless the activity is exempt from Section 404 regulation.

Safe Drinking Water Act

The Safe Drinking Water Act, passed by Congress in 1974 for the purpose of protecting public health, regulates public drinking water supplies derived from various sources, including rivers, lakes, reservoirs, springs, and groundwater wells. The federal Safe Drinking Water Act is implemented by the U.S. EPA. The Safe Drinking Water Act is discussed in more detail in Chapter 2, Section 2.4.1.

Raker Act

The Raker Act, passed by Congress in 1913, granted to the City and County of San Francisco (CCSF) rights-of-way to certain public lands, including public lands in Yosemite National Park and Stanislaus National Forest, to develop water and power. (See Chapter 2, Section 2.4.2, for further description.)

Wilderness Act

The Wilderness Act,[1] enacted by Congress in 1964, established a National Wilderness Preservation System composed of federally owned and designated wilderness areas. The purpose of the National Wilderness Preservation System is to preserve wilderness areas for future use and enjoyment. Human activities in designated wilderness areas are limited to those that leave no long-term impact on the land or that have little or no effect on the natural resources of the area. With limited exceptions, no commercial enterprises or permanent roads are allowed within a wilderness area.

The portion of the Tuolumne River watershed that drains into Hetch Hetchy Reservoir (459 square miles) is entirely within Yosemite National Park, and approximately 95 percent of the watershed is federally designated wilderness. This designation provides unique measures of protection to the watershed. The NPS manages Yosemite National Park to preserve the resources that contribute to Yosemite's uniqueness and attractiveness in accordance with the goals and principles of the 1964 Wilderness Act (USFS, 1986).

Wild and Scenic Rivers Act

In 1968, Congress enacted the Wild and Scenic Rivers Act[2] for the purpose of preserving the free-flowing characteristics and outstanding values of designated rivers while allowing uses compatible with the management goals of designated rivers. Specifically, designation as a Wild and Scenic River prohibits the federal government from licensing or permitting hydroelectric dams or major diversions along the designated reaches. The act also provides for the management of federal public lands within the corridor of the designated river. Segments are classified into one of three designations that are based on the level of existing development (and not on a description of any particular values): *wild* segments are wild, unroaded, and undeveloped; *scenic* segments are generally undeveloped, but may have occasional road crossings and riverside structures that are visually screened from the river; and *recreational* segments are generally developed with roads, bridges, and structures (Friends of the River, 2007).

1 The Wilderness Act of 1964, Pubic Law Sections 88–577; 16 United States Code Sections 1131–1136.
2 The California Wild and Scenic Rivers Act of 1972 (Public Resources Code, Sections 5093.50 et seq.), modeled after the federal Wild and Scenic Rivers Act, does not designate any rivers that would be affected by WSIP projects.

In 1984, Congress designated 83 miles of the main stem of the Tuolumne River, from its source to Don Pedro Reservoir, as a wild and scenic river, as shown in **Figure 5.2-1**. The classification and mileage of the designated reach is as follows: 47 miles wild, 23 miles scenic, and 13 miles recreational. A total of 54 miles of the designated river are located within Yosemite National Park (not including Hetch Hetchy Reservoir, which was excluded from the designation), and 29 miles of the designated river are located outside of Yosemite National Park (USFWS, 2007). In accordance with the Wild and Scenic Rivers Act, federal agencies are required to prepare a comprehensive management plan for designated rivers within three years of designation to guide future management decisions. The designation does not affect any rights, obligations, privileges, or benefits granted under the Raker Act. The NPS administers wild and scenic rivers that flow wholly or partly within the boundaries of the national park system; the Secretary of Agriculture administers wild and scenic rivers that flow wholly or partly within the boundaries of national forests.

Endangered Species Act

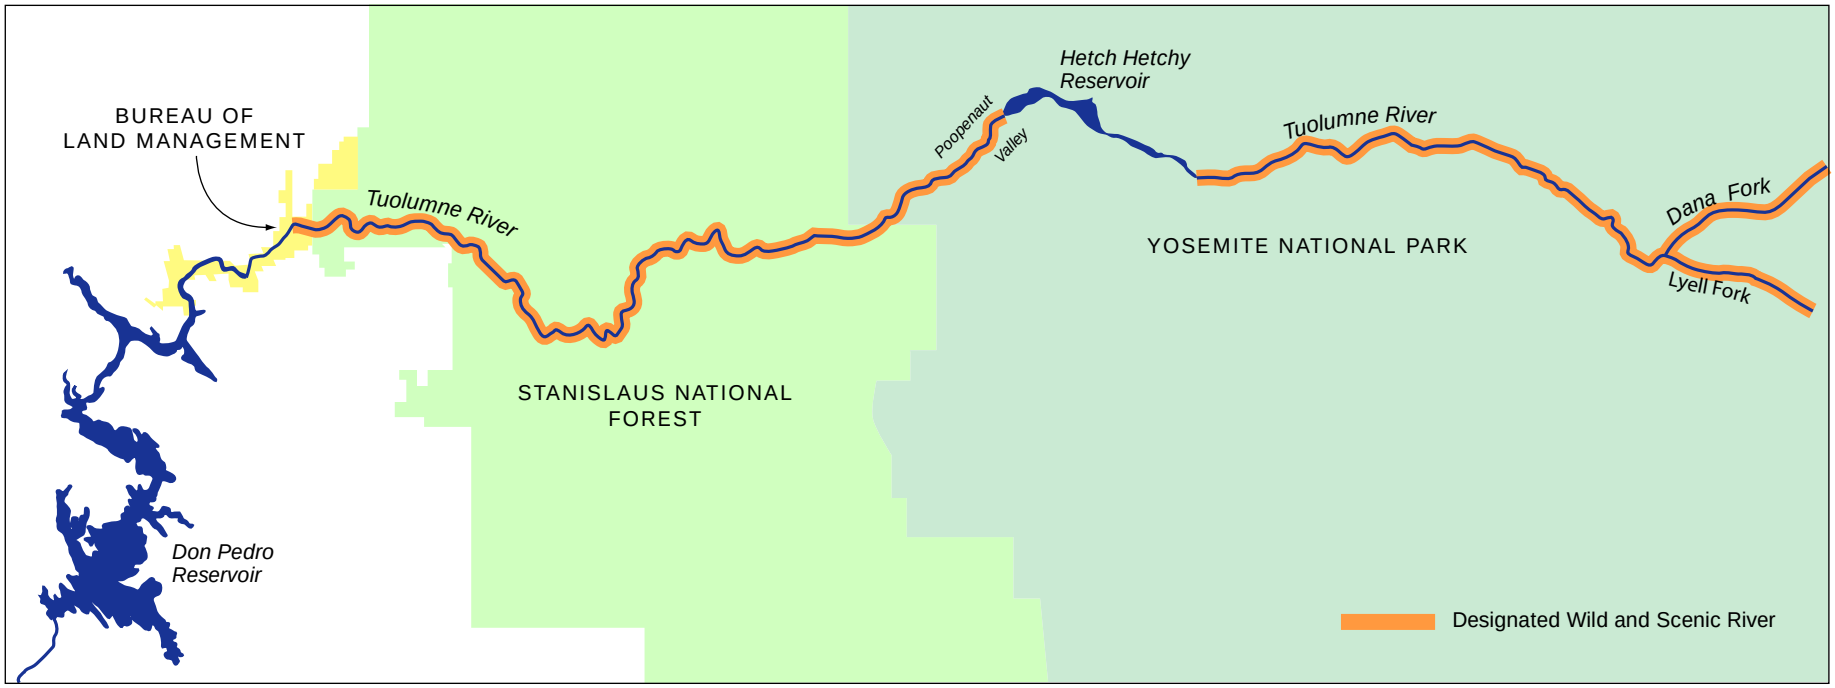
The Federal Endangered Species Act of 1973 provides broad protection for species of fish, wildlife, and plants that are listed as threatened or endangered in the U.S. or elsewhere. Provisions of the act provide for the listing of species, preparation of recovery plans, and designation of critical habitat for listed species. Federal agencies must follow the act's provisions when taking actions that may jeopardize listed species. The Federal Endangered Species Act is enforced by the USFWS and NMFS. The California Endangered Species Act generally parallels the main provisions of the federal law and is administered by the California Department of Fish and Game (CDFG).

Federal Power Act

The Federal Power Act of 1920 requires hydropower project owners to obtain a license from the Federal Energy Regulatory Commission (FERC). Among other purposes, FERC is charged with protecting fish and wildlife, including related spawning grounds and habitat, as well as mitigating impacts on recreation. The Federal Power Act authorizes the USFWS and NMFS to issue mandatory fishway prescriptions to ensure adequate protection, mitigation, and enhancement of fish and wildlife and their habitats. The Hetch Hetchy Project is statutorily exempt from provisions of the Federal Power Act. The Don Pedro Project is subject to FERC jurisdiction for its hydropower operations.

New Don Pedro Project FERC Settlement Agreement

Executed in 1995 by Tuolumne River stakeholder groups, the FERC Settlement Agreement established a revised instream flow schedule for New Don Pedro Project operation and outlined a strategy for recovery of Tuolumne River Chinook salmon (TID/MID, 1996). The revised flow schedule and a monitoring program were subsequently ordered by FERC in 1996, when FERC amended the license for the New Don Pedro Project to incorporate the settlement agreement flow schedules. The agreement requires implementation of measures to improve Chinook salmon habitat and increase populations, including increased flows, habitat rehabilitation and improvement, and measures to improve smolt survival. The FERC order required TID and MID



SOURCE: ESA + Orion

Figure 5.2-1
Tuolumne River, Wild and Scenic River Designation

to file a 10-year report on the success of the flow modifications, and non-flow mitigation measures were reevaluated in 2005 (TID/MID, 2005). In 2000, the Tuolumne River Technical Advisory Committee (TRTAC), completed the *Habitat Restoration Plan for the Lower Tuolumne River Corridor* (TRTAC, 2000) as the primary planning product of the Settlement Agreement. The restoration plan is to be used by the Tuolumne River Technical Advisory Committee to help fulfill its obligations to FERC under the Settlement Agreement. It is a technical resource document intended to aid in identifying areas of potential habitat improvement and to provide guidance for restoring or rehabilitating these areas (see Section 5.2.3 for further description of the plan). The restoration plan has not been formally adopted by any federal, state or local agency.

State Agencies

California Department of Water Resources

The Department of Water Resources (DWR) is responsible for the overall management of California's water resources. Duties performed by the DWR include, but are not limited to, developing strategies for managing the state's water resources, including updates of the *California Water Plan*; operating and maintaining the State Water Project; and providing policy direction and legislative guidance on water and energy issues.

The DWR owns and operates Del Valle Reservoir in the Alameda Creek watershed. The DWR constructed this facility primarily for flood control and recreational purposes as well as to provide regulatory flows in the South Bay Aqueduct (DWR, 1997). Since 1969, through a series of agreements among the DWR, Alameda County Water District, and Zone 7 Water Agency, local water has been stored for later release and subsequent beneficial use by the water districts under their SWRCB permits. The disposition of stored local inflow is determined by the districts. Water can be released into Arroyo del Valle, released into the South Bay Aqueduct, exchanged for an equivalent amount of South Bay Aqueduct water, or any combination of the foregoing (DWR, 1997). Under the current agreement, the DWR is allowed to use local inflow at times when the districts cannot use all or part of this supply.

California Department of Health Services

The California Department of Health Services (DHS) is responsible for the enforcement of the Safe Drinking Water Act and regulation of public water systems through the Drinking Water Program. DHS activities include field inspections of water systems, source water assessments, issuance of operating permits, review of plans and specifications for new facilities, enforcement actions for noncompliance with laws and regulations, and promotion of water system security. The DHS also regulates the use of recycled water by establishing water quality standards and treatment reliability criteria for recycled water under Title 22 of the California Code of Regulations.

State Water Resources Control Board

The SWRCB, created in 1967, has the primary authority over state water rights and water quality policy. The SWRCB is responsible for the enforcement of the Porter-Cologne Water Quality Control Act (Division 7 of the California Water Code), which deals with potential discharges into

water bodies that could result in adverse impacts on water quality. The regulations enacted by the SWRCB are enforced by the nine regional boards at the local and regional level.

California Regional Water Quality Control Boards

The mission of the California RWQCBs is to develop and enforce water quality objectives and implementation plans that will best protect the beneficial uses of the state's waters, recognizing local differences in climate, topography, geology, and hydrology. The RWQCBs engage in a number of water quality functions in their respective regions. One of the most important is preparing and periodically updating WQCPs. The San Francisco Bay and Central Valley RWQCBs are the relevant boards reviewing WSIP projects.

State Statutes and Agreements

California Water Code

The California Water Code contains the fundamental provisions related to management of the state's water resources. The California Water Code requires that water resources of the state be put to beneficial use to the fullest possible extent, and that waste, unreasonable use, or unreasonable method of use be prevented. Acts contained under the California Water Code relevant to the WSIP include the Water Reuse Law, Urban Water Management Planning Act, California Water Recycling Act, and Wholesale Regional Water System Security and Reliability Act.

Urban Water Management Planning Act

The Urban Water Management Planning Act, enacted in 1983 by the state legislature, requires urban water suppliers that provide water to 3,000 or more customers, or that provide over 3,000 acre-feet of water annually, to prepare an urban water management plan (UWMP). UWMPs are updated every five years and must describe and evaluate existing and planned sources of water supply; discuss the reliability of the water supply with respect to seasonal or climatic shortages; describe demand management measures to be implemented by the water supplier; and provide an implementation strategy and schedule for any future planned water supply projects and water supply programs. The act is administered by the DWR (California Water Code Sections 10620–10621).

Wholesale Regional Water System Security and Reliability Act and Water First Policy

California Assembly Bill No. 1823 (AB 1823), known as the Wholesale Regional Water System Security and Reliability Act, imposed various requirements on wholesale water systems. The bill, adopted in 2002, required the SFPUC, acting on behalf of the CCSF, to adopt a capital improvement program by February 1, 2003; to adopt an emergency response plan by September 1, 2003; to distribute available water during any interruption to customers on an equitable basis; to continue operating reservoirs in Tuolumne County in a manner that ensures hydroelectric power generation does not cause any reasonably anticipated impacts on water service; and to assign a higher priority to water Bay Area deliveries than to power generation (California Water Code Sections 73500–73514). The act also includes the SFPUC's Water First Policy.

The Water First Policy, contained in Section 73504(b) of the California Water Code, was formally established in the San Francisco City Charter following adoption of AB 1823 by the state legislature and approval of Proposition E by San Francisco voters. Under this policy, the SFPUC must place water service to the Bay Area before the generation of hydroelectric power. (See Chapter 2, Section 2.4.3 for additional information on AB 1823.)

Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act was passed by the state legislature in 1969 and is the primary statute covering the quality of waters in California. The act specifies water quality provisions and discharge requirements for regulating the discharge of waste that could affect the quality of state waters. Under the act, the SWRCB has the ultimate authority over state water rights and water quality policy. The nine RWQCBs are responsible for the oversight of water quality on a day-to-day basis at the local and regional level.

California Safe Drinking Water Act

The California Safe Drinking Water Act, administered by the DHS, strengthens the minimum requirements found in the federal Safe Drinking Water Act and establishes drinking water standards that are at least as stringent as, and sometimes more stringent than, those established under the federal act. California's development of drinking water standards for MTBE is an example of its more aggressive standards.

San Joaquin River Agreement

The 1995 Water Quality Control Plan (WQCP) for the San Francisco/Sacramento–San Joaquin Delta Estuary included water quality and flow objectives pertaining to the San Joaquin River basin. Disputes over the science supporting the flow objective for the San Joaquin River as measured in Vernalis (shown in Section 5.3, Figure 5.3-1) led to the development of an experimental program to develop an adaptive fishery management plan and the water supplies to support that plan. The San Joaquin River Agreement, adopted by the SWRCB in April 1998, provided the basis for development of the Vernalis Adaptive Management Program (VAMP) and identified where much of the water to support the VAMP study would be obtained (specifically, from the San Joaquin River Group Authority). The VAMP is an experimental management program designed to protect juvenile Chinook salmon migrating from the San Joaquin River through the Delta (San Joaquin River Group Authority, 1999). The VAMP study is summarized below in Section 5.2.3 and discussed in more detail in Section 5.3.1.

Local and Regional Agencies

City and County of San Francisco

As a department of the CCSF, the SFPUC has authority over the management, use, and control of the regional water system pursuant to the San Francisco City Charter, Section 8B.121. Chapter 3, Section 3.3, presents the mission of the SFPUC relative to the objectives of the WSIP, and Section 3.13 describes the role of the CCSF and its various departments with respect to the actions and approvals required for adoption of the WSIP.

Alameda Creek Watershed Regional Agencies

In addition to the CCSF, three regional resource agencies have jurisdiction within the Alameda Creek watershed. There are no local or regional resource agencies with jurisdiction over areas within the Tuolumne and Peninsula watersheds or the Westside Groundwater Basin (beyond those described in Chapter 3, Section 3.13, related to the conjunctive-use program) that could be affected by the proposed water supply and system operations.

Alameda County Flood Control and Water Conservation District

The Alameda County Flood Control and Water Conservation District (ACFCWCD) works specifically to protect county citizens from flooding hazards. The ACFCWCD is responsible for planning, designing, and inspecting flood control projects; maintaining flood control infrastructure; assisting in planning new developments to preserve the integrity of the flood control system; and providing public outreach and enforcement of pollution control regulations governing county waterways.

Zone 7 Water Agency

Zone 7 Water Agency, one of 10 active zones of the ACFCWCD, covers the eastern portion (425 square miles) of Alameda County, including Pleasanton, Livermore, and Dublin. Zone 7's entire service area lies within the Alameda Creek watershed. Unlike the other zones, Zone 7 was created by state law and has its own board of directors. Zones 7's water resource management responsibilities include providing a wholesale treated drinking water supply, monitoring and protecting surface water and groundwater quality, operating and maintaining a water treatment system, and managing floodwaters and stormwater for public safety and protection of property. In September 2005, Zone 7 adopted the updated *Urban Water Management and Water Shortage Contingency Plan*, which addresses operations as well as water supply and demand.

Zone 7 is the water quality management agency for the Alameda Creek watershed above the town of Niles. The agency does not generally participate in the management of SFPUC lands, with the exception of managing groundwater activities and monitoring development in the Zone 7 service area for erosion potential and channel capacity impacts through the CEQA process.

Zone 7 also serves as a water wholesaler, with supplies originating from local groundwater sources, imported water from the State Water Project, and local water stored in Del Valle Reservoir. The agency is also responsible for mitigating flood hazards in its service area and has undertaken channelization projects on sections of Arroyo de la Laguna, Arroyo del Valle, and Arroyo Mocho.

East Bay Regional Park District

The East Bay Regional Park District's (EBRPD) Sunol and Ohlone Regional Wilderness preserves are within the watersheds of Alameda Creek (below Calaveras Reservoir) and San Antonio Reservoir, respectively. Watershed management activities in these preserves can affect water quality in those receiving waters. The EBRPD has worked with the SFPUC on a number of fish enhancement projects in the watershed, including cattle fencing to keep livestock out of sensitive riparian areas.

Local Regulation

The only local regulation relevant to the WSIP is the San Francisco City Charter.

San Francisco City Charter

The San Francisco City Charter was adopted on November 7, 1995, and became effective July 1, 1996. In November 2002, the voters adopted Proposition E, which amended the charter as it relates to the SFPUC. The charter establishes many of the procedures and requirements for initiative ordinances and declarations of policy. Where the charter does not address a particular aspect of the initiative process, applicable provisions of California law apply. As specified in Section 8B.122 of the charter, the SFPUC is required to develop, periodically update, and implement programs consistent with the following goals and objectives related to water resources:

(1) Provide water and clean water services to San Francisco and water service to its wholesale customers while maintaining stewardship of the system by the City;

(2) Establish equitable rates sufficient to meet and maintain operation, maintenance, and financial health of the system;

(3) Provide reliable water and clean water services and optimize the systems' ability to withstand disasters;

(4) Protect and manage lands and natural resources used by the SFPUC to provide utility services consistent with applicable laws in an environmentally sustainable manner. Operate hydroelectric generation facilities in a manner that causes no reasonably anticipated adverse impacts on water service and habitat;

(5) Develop and implement priority programs to increase and to monitor water conservation and efficiency systemwide;

(6) Utilize state-of-the-art innovative technologies where feasible and beneficial;

(7) Develop and implement a comprehensive set of environmental justice guidelines for use in connection with its operations and projects in the city;

(8) Create opportunities for meaningful community participation in development and implementation of the SFPUC's policies and programs; and

(9) Improve drinking water quality with a goal of exceeding applicable drinking water standards if feasible.

5.2.3 Relevant Plans, Policies, and Planning Actions

Regional Natural Resource Protection Plans

Many of the federal and state statutes and agreements summarized in Section 5.2.2 form the basis for development of the regional natural resource protection plans and policies described in this section. These plans and policies play an important role in the SFPUC's current and future operation of the regional water system by establishing guidelines for the protection of fish,

wildlife, and riparian habitat and by setting enforceable water quality objectives/criteria for surface waters potentially affected by the regional water system. As indicated below, the plans and policies are in various stages of development; only some of the plans and policies are adopted and many are either under development or in a study or experimental stage.

Tuolumne Wild and Scenic River Management Plan

The *Tuolumne Wild and Scenic River Management Plan* (Wild and Scenic Plan) was approved in 1986 and is administered by the U.S. Forest Service, Pacific Southwest Region. The Wild and Scenic Plan, applicable only to the 29 miles of the Tuolumne Wild and Scenic River located outside of Yosemite National Park (see Figure 5.2-1), provides direction for managing the use of federal lands within the boundaries of the designated corridor and for protecting the unique qualities of the designated river. The Wild and Scenic Plan does not apply to the exercise of the CCSF's water rights under the existing Raker Act grant, as stated in the Wild and Scenic Rivers Act (Section 3 [a] [53] Tuolumne, California) as follows: "Nothing in this section is intended or shall be construed to affect any rights, obligations, privileges, or benefits granted under any prior authority of law including chapter 4 of the Act of December 13, 1913, commonly referred to as the Raker Act (38 Stat. 242) and including any agreement or administrative ruling entered into or made effective before the enactment of this paragraph [September 28, 1984]."

The Wild and Scenic Plan includes general management objectives and guidelines applicable to the entire designated corridor as well as reach-specific management prescriptions and recreational improvement opportunities assigned to particular management areas. All land uses within the designated corridor are subject to the provisions of the Wild and Scenic Plan. Selected management objectives, standards, and guidelines applicable to the entire designated corridor are listed below.

Management Objectives

Physical Setting Opportunities – Fish and Wildlife

1. Provide habitat for management of indicator species including threatened, endangered, and sensitive species. These include peregrine falcon, bald eagle, mule deer, western gray squirrel, yellow warbler, and Sierra Nevada red fox.

Physical Setting Opportunities – Timber

1. Manage vegetation to protect and enhance Wild and Scenic River values, placing special emphasis on protecting streamside vegetation.

Physical Setting Opportunities – Water

1. Maintain or improve the existing high water quality for fisheries, aesthetics, and other ecological considerations. Give priority to protection of water quality in cases of conflict with other resource uses. Prevent alteration of natural channels or stream banks that would significantly affect the free-flow of water, the appearance of the stream, fish habitat, or water quality.

Physical Setting Opportunities – Lands

2. Work with proponents and operators of hydroelectric projects outside of the corridor to provide mitigation to eliminate or minimize adverse environmental impacts and to provide for recreation opportunities created by the project that will meet the objectives of this management plan.

Managerial Setting Opportunities

5. Manage the Tuolumne Wild and Scenic River and its immediate environment to preserve its free-flowing condition and to protect its outstandingly remarkable values.[3] Provide opportunities for public recreation and other resources based on the classification of each river segment.

Standards and Guidelines

Fish and Wildlife

- Fish and Wildlife Habitat Coordination (C1-WS). Maintain and enhance habitat for fish and wildlife species.

- Stream Fisheries Habitat Improvement and Maintenance (C2-WS). Provide medium- to high-quality habitat for resident trout species (rainbow, brown, and brook) according to the habitat capability model.

- Riparian and Meadow Vegetation Management (C4-WS). Provide cover and forage for fish and wildlife species associated with riparian habitats by maintaining medium- to high-habitat quality according to the Habitat Quality Criteria for Riparian Habitat.

Specific impacts on potentially affected resources covered in this plan—including water, fish and wildlife, vegetation, recreational, and visual resources—resulting from implementation of the proposed WSIP water supply and system operations are analyzed in this chapter in the corresponding subsections of Section 5.3.

Tuolumne Wild and Scenic River Comprehensive Management Plan, General Management Plan for Yosemite National Park, and Wilderness Management Plan

The NPS is currently in the process of preparing a comprehensive management plan for the 54 miles of designated wild and scenic river within Yosemite National Park, as mandated by the Wild and Scenic Rivers Act. This reach of designated river includes portions of the river extending from the Tioga Pass Entrance and Lyell Canyon to the Poopenaut Valley, as shown in Figure 5.2-1. The lands immediately surrounding Hetch Hetchy Reservoir are not included in the plan area; environmental stewardship of these lands is the responsibility of the SFPUC and is performed in coordination with the NPS, as described in Chapter 2, Section 2.3.8. However, the six-mile reach of the Tuolumne River, downstream of Hetch Hetchy Reservoir, that passes through the Poopenaut Valley is covered under this plan.

[3] Outstandingly remarkable values are defined by the Wild and Scenic Rivers Act as the unique characteristics that make a river worthy of special protection.

The intended purpose of the plan currently under development, known as the *Tuolumne Wild and Scenic River Comprehensive Management Plan* (Tuolumne River Plan), is to establish the overall goals and vision for the river corridor. It will provide broad, conceptual-level management objectives that may amend the *General Management Plan for Yosemite National Park* (1980) for the river corridor. The Tuolumne River Plan is not intended to include specific implementation strategies or plans. Concurrent with the Tuolumne River Plan, the NPS is also developing an implementation plan for Tuolumne Meadows that will be guided by the Tuolumne River Plan. Public scoping related to development of the two plans was completed in September 2006, and the draft environmental impact statement is scheduled for release in 2008, with the final report expected in 2009 (NPS, 2006b, 2007).

As part of the development of the Tuolumne River Plan, the NPS developed a draft report entitled *Tuolumne Wild and Scenic River Outstandingly Remarkable Values* (NPS, 2006a). This report presents the proposed revision of the outstandingly remarkable values for the portion of the Tuolumne Wild and Scenic River within Yosemite National Park. Outstandingly remarkable values are identified for natural (ecologic, hydrologic, geologic, and biologic), sociocultural (prehistoric, historic, scenic, and recreational), and scientific values by river segment and for the corridor as a whole. A final report will incorporate comments received during public scoping and review of the draft Tuolumne River Plan and become the foundation for the final Tuolumne River Plan. The *Outstandingly Remarkable Values* includes specific description of cultural, historic, hydrologic, geologic, biologic, scenic, and recreational attributes of the reach of the Tuolumne River below Hetch Hetchy Reservoir, including the Poopenaut Valley, potentially affected by the proposed water supply and system operations.

Much of the area around the Tuolumne River is federally designated as wilderness and is covered under the NPS's *Wilderness Management Plan*. The general guidance and direction for the *Wilderness Management Plan* currently derive from the *General Management Plan for Yosemite National Park*, the Wilderness Act, and NPS policy. When the *Wilderness Management Plan* is updated, the NPS will incorporate guidance and direction established by the Tuolumne River Plan.

Although the Tuolumne River Plan is still under development, specific impacts on potentially affected resources to be covered in the plan—including water, biological, recreational, and visual resources—resulting from implementation of the proposed WSIP water supply and system operations are analyzed in this chapter in the corresponding subsections of Section 5.3.

Vernalis Adaptive Management Program

The VAMP, a product of the San Joaquin River Agreement and officially initiated as part of SWRCB Decision 1641, is a 12-year experimental adaptive management program to study the effects of alterations in San Joaquin River flows and Delta pumping rates on the migration of salmon within the San Joaquin River basin. Under the VAMP, a barrier was installed at the head of Old River, and different amounts of water are released down the San Joaquin River, curtailing exports from the Delta by the State Water Project and Central Valley Project to varying degrees for one month in the spring when juvenile salmon are migrating. Information on the effects of different river flow and export rates on migrating salmon is being gathered and may be used to

establish future standards for their protection. The VAMP is administered by the parties to the San Joaquin River Agreement, including the U.S. Bureau of Reclamation, DWR, CDFG, USFWS, and San Joaquin River Group Authority.

The VAMP is discussed in this chapter because the WSIP would affect flows in the Tuolumne River, a tributary to the San Joaquin River and the Sacramento–San Joaquin Delta. Specific impacts on potentially affected resources covered in this plan—including flows in the San Joaquin River—resulting from implementation of the proposed WSIP water supply and system operations are discussed in Section 5.3.1 of this chapter. The VAMP is not an adopted plan, but rather a temporary experimental program; however, it is expected that either the VAMP or a "VAMP-like" program will be continued when the current program expires.

Habitat Restoration Plan for the Lower Tuolumne River Corridor

Under the 1995 FERC Settlement Agreement (described above and in Chapter 2, Section 2.5.2), the TRTAC is responsible for developing and implementing a Chinook salmon restoration plan and salmon management and habitat restoration activities as part of the strategy to address a decline in fall-run Chinook salmon in the lower Tuolumne River (FERC, 1996). The *Habitat Restoration Plan for the Lower Tuolumne River Corridor* (TRTAC, 2000) is a technical resource document, not an adopted plan, intended to aid the TRTAC in identifying areas of potential habitat improvement and in restoring or rehabilitating these areas.

The restoration plan integrates salmon ecology and geomorphic and hydrologic processes into a riverwide and reach-specific plan. The plan includes goals and strategies to guide future management, specific monitoring objectives, a comprehensive list of all potential restoration sites and actions, and conceptual designs for 14 high-priority restoration projects.

The restoration plan describes how cumulative water storage and diversion projects in the lower Tuolumne River watershed have led to a reduction in annual water yield below La Grange Dam, reductions in the magnitude and variability of the annual hydrograph,[4] and a reduction in the magnitude, duration, and frequency of winter floods. The restoration plan promotes the recovery of Chinook salmon and the river's natural animal and plant communities through the reestablishment of fluvial geomorphic functions, processes, and characteristics. The plan includes the following riverwide restoration goals for the Tuolumne River:

- A continuous river floodway from La Grange Dam to the confluence of the San Joaquin River
- A continuous riparian corridor from La Grange Dam to the San Joaquin River confluence, with a minimum width of 500 feet and a width of up to 2,000 feet near the San Joaquin River
- A dynamic alluvial channel maintained by flood hydrographs of variable magnitude and frequency adequate to periodically initiate geomorphic processes
- The establishment of variable stream flows to benefit salmon and other aquatic resources

[4] A chart that illustrates the pattern of flow in a stream as a function of time.

- Chinook salmon habitat created and maintained by natural processes, sustaining a resilient, naturally reproducing Chinook salmon population

- Self-sustaining, dynamic, native woody riparian vegetation

- Continual revision of the adaptive management program, addressing areas of scientific uncertainty that will improve our understanding of river ecosystem processes and refine future restoration and management

Specific impacts on potentially affected resources covered in this plan—including water, geomorphological, biological, recreational, and visual resources—resulting from implementation of the proposed WSIP water supply and system operations are addressed in this chapter in the corresponding subsections of Section 5.3, and information from this plan is used as a resource for mitigation strategies.

Water Quality Control Plans

Each RWQCB is required to develop, adopt, and implement a Water Quality Control Plan (WQCP), also known as a Basin Plan, for its respective region. The WQCP is the master policy document that contains descriptions of the legal, technical, and programmatic bases of water quality regulation. WQCPs identify beneficial uses of surface waters and groundwater within the corresponding region; specify water quality objectives and standards for both surface water and groundwater; and develop the actions necessary to maintain the standards in order to control nonpoint and point sources of pollutants to the state's waters.

WQCPs are adopted and amended by the RWQCBs and approved by the SWRCB. Adoption of or revisions to the surface water objectives/standards contained in the WQCPs are subject to U.S. EPA approval. All discretionary projects requiring permits from the RWQCB (i.e., waste discharge requirements and National Pollutant Discharge Elimination System permits) must implement WQCP requirements, taking into consideration the beneficial uses to be protected.

Two adopted WQCPs govern the management of surface and ground waters that could be affected by proposed WSIP system operations. The Central Valley WQCP covers the Sacramento and San Joaquin River basins, including the Tuolumne River watershed. The San Francisco Bay/Delta WQCP covers those portions of Alameda, Contra Costa, Marin, Napa, San Mateo, San Francisco, Santa Clara, Solano, and Sonoma Counties that drain to the San Francisco Bay Estuary, including the Delta, as well as areas draining to the Pacific Ocean; this plan includes the Alameda Creek watershed, the Peninsula watershed (including San Mateo and Pilarcitos Creeks), and the Westside Groundwater Basin. Water objectives/standards contained in the WQCPs are enforceable against the SFPUC. Specific impacts on water quality associated with implementation of the proposed WSIP water supply and system operations are analyzed by watershed in Sections 5.3.3, 5.4.3, and 5.5.3 of this chapter.

Regional Habitat Conservation Plans

Habitat conservation plans (HCPs) are land use and biological planning documents that provide comprehensive, long-term conservation measures for species listed as threatened or endangered under the California and Federal Endangered Species Acts, or for species that could be listed in the future. One adopted HCP covering an area that could be affected by WSIP implementation was identified (see separate discussion below of SFPUC HCPs). In 1995, the City of Waterford prepared an HCP for the incidental take of valley elderberry longhorn beetle (VELB) on the Tuolumne River at the discharge point of its wastewater treatment facility, located between La Grange Dam and the city of Modesto. The HCP involved the removal of about 150 elderberry bushes on five acres and the installation of over 800 small bushes.

Alameda Creek Watershed Management Planning Efforts

Multiple stakeholders in the Alameda Creek watershed area, including the SFPUC, Alameda County Water District, ACFCWCD, Zone 7, EBRPD, and various environmental interest groups, are involved in ongoing planning efforts to manage the Alameda Creek watershed. Although no specific plans have been adopted, planning efforts include the development of a comprehensive management plan for the watershed; the plan, which is being prepared in conjunction with the Alameda Creek Fisheries Restoration Workgroup, will focus on restoring steelhead to the Alameda Creek watershed. In October 2006, 17 public agencies and nonprofit organizations[5] signed a formal agreement to collaborate on stream flow requirements for steelhead, other native fish and wildlife, and drinking water supplies (Alameda Creek Fisheries Restoration Workgroup, 2006). This planning effort is discussed in the Alameda Creek watershed fisheries section and in cumulative analysis of the WSIP water supply and system operations, in Sections 5.4.5 and 5.7, respectively.

Pilarcitos Creek Watershed Restoration Plan

Developed in coordination with the California Department of Fish and Game, Regional Water Quality Control Board, and a citizen's advisory committee, the *Pilarcitos Creek Restoration Plan* (Philip William & Associates, Ltd., 1996) details the major issues of concern regarding Pilarcitos Creek and its tributaries, and prioritizes alternatives to significantly enhance the physical and biological attributes of the watershed. The alternatives involve reducing sedimentation in the creek and its tributaries, enhancing fish migration and rearing and riparian habitat, and providing educational resources. Not an adopted plan, this document and its subsequent updates serve as a guide to restoration projects and related activities in the Pilarcitos watershed. It is considered in this chapter with respect to providing documentation of existing conditions in the Pilarcitos watershed and potential mitigation strategies for potential impacts associated with the WSIP water supply option and system operations.

[5] Participating organizations in the Alameda Creek Fisheries Restoration Workgroup include: the Alameda County Water District, Alameda County Flood Control and Water Conservation District, Alameda Creek Alliance, Coastal Conservancy, Zone 7, Pacific Gas and Electric Company, SFPUC, Alameda County Resource Conservation District, American Rivers, California Department of Fish and Game, East Bay Regional Park District, National Marine Fisheries Service, Natural Resources Defense Council, San Francisco Bay Regional Water Quality Control Board, U.S. Army Corps of Engineers, U.S. Natural Resources Conservation Service, and U.S. Fish and Wildlife Service.

Pilarcitos Creek Integrated Watershed Management Plan

The Pilarcitos Creek Restoration Workgroup[6] is currently developing the *Pilarcitos Creek Integrated Watershed Management Plan*, the intended purpose of which is to "determine how to more effectively manage the competing beneficial uses of water from Pilarcitos Creek and promote balanced solutions that satisfy environmental, public health, recreational, and economic interests. An important component of the plan will be an assessment of existing conditions and a strategy for addressing the actions necessary for the protection and restoration of [steelhead trout] and other species of concern that depend on aquatic and riparian habitats throughout the watershed" (San Mateo County Resource Conservation District, 2006). The plan will build on the 1996 *Pilarcitos Creek Restoration Plan*, and a Memorandum of Understanding has been developed among the 19 participants in the workgroup to outline the process for developing the plan (Pilarcitos Creek Restoration Workgroup, 2007). It is expected that the *Pilarcitos Creek Integrated Watershed Management Plan* will be completed in 2008. This plan is considered in the cumulative analysis of the WSIP water supply and system operations, as discussed in Section 5.7.

City and County of San Francisco Plans and Policies

Chapter 4, Section 4.2, Plans and Policies, provides an overview of the relationship of CCSF planning documents to the WSIP and discusses the specific CCSF plans and policies that pertain to the WSIP facility improvement projects. This section focuses on those plans and polices that relate to the WSIP water supply and system operations.

San Francisco General Plan

Section 4.2.2 provides an overview of the San Francisco General Plan. Although the majority of policies contained in the general plan were developed for lands within San Francisco and are not generally relevant to extraterritorial lands, several policies and objectives provided in the Environmental Protection Element are relevant to the proposed operational changes and sources of water supply under the WSIP. The Fresh Water sub-element of the Environmental Protection Element of the San Francisco General Plan includes objectives aimed at the protection of freshwater resources (Objective 6) in conjunction with responsible utilization of these resources for water supply (Objective 5). Policies associated with the reliability of the regional water system include Policy 5.1 and Policy 5.2. Policy 5.3 and Policy 5.4 address water quality; Policy 6.1 specifies the continued implementation of a leak detection program; and Policy 6.2 deals with water reclamation. The Flora and Fauna sub-element of the Environmental Protection Element deals with the protection of plant and animal life (Objective 8) and specifies the protection of plant and animal species and their habitats through coordination with animal protection programs (Policy 8.1, Policy 8.2, Policy 8.3). Specific impacts on potentially affected

[6] Participating organizations in the Pilarcitos Creek Restoration Workgroup include: the SFPUC, California State Parks, San Mateo County Resource Conservation District, San Francisco Bay Regional Water Quality Control Board, Pilarcitos Creek Advisory Council, City of Half Moon Bay, Coastside County Water District, Committee for Green Foothills, Gulf of the Farallones National Marine Sanctuary, Half Moon Bay Fishermans Association, Midpeninsula Regional Open Space District, California Department of Fish and Game, Monterey Bay National Marine Sanctuary, National Marine Fisheries Service, Peninsula Open Space Trust, Pilarcitos Creek Advisory Committee, San Mateo County Farm Bureau, Sewer Authority Mid-Coastside, and Surfrider Foundation–San Mateo Chapter.

resources covered in this plan—including water and biological resources—resulting from implementation of the WSIP water supply and system operations are analyzed by watershed in the corresponding sections of this chapter.

San Francisco Sustainability Plan

The San Francisco Board of Supervisors endorsed the *San Francisco Sustainability Plan* in 1997, but has not committed the City to perform the actions addressed in the plan. The plan serves as a blueprint for sustainability, with many of its individual proposals requiring further development and public comment. The underlying goals of the plan are to maintain the physical resources and systems that support life in San Francisco and to create a social structure that will allow such maintenance. The plan is divided into 15 topic areas, 10 that address specific environmental issues (air quality; biodiversity; energy, climate change, and ozone depletion; food and agriculture; hazardous materials; human health; parks, open spaces and streetscapes; solid waste; transportation; and water and wastewater), and five that are broader in scope and cover many issues (economy and economic development, environmental justice, municipal expenditures, public information and education, and risk management). Under the topic "Water," there are goals addressing water reuse, water quality, adequacy of water supply, groundwater supply, and infrastructure. Each topic area in the plan has a set of indicators to be used over time in determining whether San Francisco is moving in a sustainable direction in that particular area (CCSF, 1997).

Specific impacts on potentially affected resources addressed in this plan—including water and groundwater resources—resulting from implementation of the WSIP water supply and system operations are analyzed by watershed in the corresponding sections of this chapter.

San Francisco Urban Water Management Plan

As discussed in *2005 Urban Water Management Plan for the City and County of San Francisco*, approximately 96 percent of the city's total water supply is provided by the SFPUC regional water system. The remaining 4 percent of the water demand is met through locally produced, nonpotable groundwater and secondary-treated recycled water used for irrigation. San Francisco overlies all or part of seven groundwater basins. Of these, only the Westside Basin and the Lobos Basin are considered adequate for municipal supplies. Groundwater pumped from wells located in Golden Gate Park and at the San Francisco Zoo is used by the Recreation and Park Department for irrigation. Tertiary-treated recycled water from the SFPUC's Southeast Water Pollution Control Plant is used on a limited basis for washdown operations.

The 2005 UWMP identifies various local water supply plans and programs that represent potential options to maximize resources and minimize the need to import water. These include ongoing implementation of water conservation programs; implementation of the *Recycled Water Master Plan* (SFPUC, 2006a), which explores additional opportunities for recycled water use in San Francisco; and implementation of the *Draft North Westside Basin Groundwater Management Plan*, which identifies several new local groundwater projects to produce an additional 2 million gallons per day of groundwater for potable purposes (SFPUC, 2005).

Information in the UWMPs of both the retail and wholesale customers of the regional water system, including the CCSF and applicable Bay Area Water Supply and Conservation Agency members, was used in the development of the WSIP level of service water supply goal for 2030.

SFPUC Watershed Management Plans

The SFPUC has adopted watershed management plans for CCSF-owned lands in the Alameda and Peninsula watersheds to provide a policy framework for activities and actions on watershed lands. Watershed lands are managed by the SFPUC Natural Resources Division, Land and Resource Management Section. The plans provide goals, policies, and management actions that address watershed activities and reflect the unique qualities of each watershed. Changes in system operations proposed under the WSIP would be required to conform to the goals, policies, and management actions contained in the Alameda and Peninsula Watershed Management Plans (WMPs) as well as applicable environmental codes and regulations. Specific impacts on affected resources covered in these plans—including water, biological, recreational, and visual resources—resulting from implementation of the WSIP water supply and system operations are analyzed for the Alameda and Peninsula watersheds in the corresponding sections of this chapter.

For both watershed plans, the SFPUC considers water quality protection as the first and foremost goal. The goals and policies are organized around the primary goal of water quality protection and six secondary goals pertaining to water supply, natural resource protection, watershed protection, land use compatibility, fiscal management, and public awareness. The primary and secondary goals were established by the Watershed Planning Committee, a group of SFPUC division and department representatives who assisted in plan development and review. The primary and secondary goals in common to both watershed management plans are as follows:

- *Primary Goal*: Maintain and Improve Source Water Quality to Protect Public Health and Safety

- *Secondary Goals*:
  - Maximize water supply
  - Preserve and enhance the ecological and cultural resources of the watershed
  - Protect the watersheds, adjacent urban areas, and the public from fire and other safety hazards
  - Continue existing compatible uses and provide opportunities for potential compatible uses on watershed lands, including educational, recreational, and scientific uses
  - Provide a fiscal framework that balances financial resources, revenue-generating activities, and overall benefits and an administrative framework that allows implementation of the watershed management plans
  - Enhance public awareness of water quality, water supply, conservation, watershed protection issues

Alameda Watershed Management Plan

The SFPUC's Alameda WMP is described in Chapter 4, Section 4.2, in the context of WSIP facilities improvement projects located in the Alameda watershed. The Alameda watershed lands are shown in Figure 2.2. The Alameda WMP provides a policy framework for the SFPUC to make consistent decisions about the activities, practices, and procedures that are appropriate on CCSF-owned lands in the Alameda watershed to protect the watershed and ensure a pure and reliable supply for San Francisco. The plan applies best management practices for the protection of water and natural resources and their conservation, enhancement, restoration, and maintenance and is intended to be used by the SFPUC as watershed management implementation guidelines.

Peninsula Watershed Management Plan

The SFPUC's Peninsula WMP is described in Chapter 4, Section 4.2, in the context of WSIP facilities improvement projects located in the Peninsula watershed. The Peninsula watershed lands are shown in Figure 2.3.The Peninsula WMP was developed in the same manner as the Alameda WMP and consists of the same primary and secondary goals as those contained in the Alameda WMP; however, some policies contained in the plan have been formulated to address the specific management issues of the Peninsula watershed.

SFPUC Habitat Conservation Plans

As part of watershed management plan implementation, the SFPUC is in the process of developing HCPs for the Alameda and Peninsula watersheds, as discussed in Chapter 4, Section 4.2. Both watersheds contain known habitat for sensitive species, and the HCPs are being developed in compliance with federal and state regulations for endangered species protection. The draft HCP for the Alameda watershed is scheduled for public review in 2007, and the draft HCP for the Peninsula watershed is scheduled for public review in 2008. Both plans will require preparation of a joint environmental impact report/environmental impact statement before the SFPUC can consider adoption and begin implementation. (See Chapter 4, Section 4.2, for additional information regarding the development of HCPs for the SFPUC Alameda and Peninsula watersheds.)

Although the HCPs are still under development, specific WSIP impacts on the resources anticipated to be covered in the plans—particularly steelhead and other federal- or state-listed biological resources—are analyzed for the Alameda and Peninsula watersheds in the corresponding sections of this chapter.

SFPUC Water Enterprise Environmental Stewardship Policy

Adopted in June 2006, the Water Enterprise Environmental Stewardship Policy established the long-term management direction for CCSF-owned lands and natural resources affected by operation of the SFPUC regional water system within the Tuolumne River, Alameda Creek, and Peninsula watersheds (SFPUC, 2006b). It also addresses rights-of-way and properties in urban surroundings under SFPUC management. The policy includes the following specifically relevant to the proposed water supply and system operations:

- The SFPUC will proactively manage the watersheds under its responsibility in a manner that maintains the integrity of the natural resources, restores habitats for native species, and enhances ecosystem function.

- To the maximum extent practicable, the SFPUC will ensure that all operations of the SFPUC water system (including water diversion, storage, and transport), construction and maintenance of infrastructure, land management policies and practices, purchase and sale of watershed lands, and lease agreements for watershed lands protect and restore native species and the ecosystems that support them.

- It is the policy of the SFPUC to operate the SFPUC water system in a manner that protects and restores native fish and wildlife downstream of SFPUC dams and water diversions, within SFPUC reservoirs, and on SFPUC watershed lands.

- Releases from SFPUC reservoirs will mimic the variation of the seasonal hydrology (e.g., magnitude, timing, duration, and frequency) of their corresponding watersheds in order to sustain the aquatic and riparian ecosystems upon which these native fish and wildlife species depend (consistent with the SFPUC mission, existing agreements, and applicable state and federal laws).

- The SFPUC will actively monitor the health of the terrestrial and aquatic habitats, both under SFPUC ownership and affected by SFPUC operations, in order to continually improve ecosystem health.

The Environmental Stewardship Policy calls for implementation and update of the Alameda and Peninsula WMPs (described above), development of habitat conservation plans for the Alameda and Peninsula watersheds (described above), and development and implementation of the Watershed Environmental Improvement Program (described in Chapter 3, Section 3.12, WSIP-Related Activities), as well as specific integration of this policy into the WSIP and individual infrastructure projects.

General Plans of Potentially Affected Counties

Chapter 4, Section 4.2.2, describes the applicability of city and county general plan policies to the WSIP facility improvement projects; much of that discussion also applies to the proposed WSIP water supply and system operations. No local agency approvals other than those of the CCSF are expected to be needed for the proposed water supply and system operations (see Chapter 3, Section 3.13). Any county required to determine consistency of a part of the WSIP with their general plan pursuant to California Government Code 65402(b) would be notified by the SFPUC prior to implementation. Notwithstanding the limited authority of cities and counties over implementation of the WSIP, where CCSF-owned facilities are sited and operated outside of San Francisco, the SFPUC seeks to work cooperatively with cities and counties to avoid conflicts with local plans and policies. For the WSIP, a key issue for local agencies that receive all or part of their water from the SFPUC is whether the WSIP adequately addresses community goals regarding water service for existing and future land uses; this topic is addressed in Section 4.2.3. A second issue of importance to local agencies is whether implementation of the WSIP would be consistent with community goals regarding resource protection. Counties in which WSIP

operations could result in surface water or groundwater hydrology impacts and/or secondary biological effects include the following:

- Tuolumne
- Stanislaus
- Alameda
- San Joaquin
- Santa Clara
- San Mateo

Table 5.2-2 presents an overview of policies and goals from these counties' general plans that address water resources management and biological resources. The issues shown in the table are addressed in the impact analyses presented in Chapter 5. The only significance criterion applicable to the impact analysis in Chapter 5 regarding WSIP compatibility with certain aspects of local land use plans and polices is "Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan." This impact is analyzed in Sections 5.3.7, 5.4.6, and 5.5.6, Terrestrial Biological Resources in the Tuolumne, Alameda Creek, and Peninsula watersheds, respectively.

TABLE 5.2-2
SUMMARY OF GENERAL PLAN POLICIES OF COUNTIES
WITH SURFACE WATER AND GROUNDWATER RESOURCES
POTENTIALLY AFFECTED BY THE PROPOSED WSIP WATER SUPPLY AND SYSTEM OPERATIONS

Resource Area	Summary Description of General Plan Policy
Water Resources Management	Preserve water resources for all beneficial uses of water; ensure the adequate quantity and quality of water for municipal and industrial uses, agriculture, recreation, fish and wildlife, and Delta outflows for salinity repulsion.
	Recognize surface water resources of state and national significance for which environmental and scenic values must be protected; minimize alteration of natural water bodies; support "properly timed, sufficient flows" in rivers.
	Protect groundwater resources.
Biological Resources	Develop comprehensive watershed management plans to assure that cumulative impacts on water quality, reservoir operations, and watershed resources are addressed and mitigated.
	Recognize and protect resources of significant biological and ecological importance; protect habitats of rare and endangered fish and wildlife species; maintain adequate stream/river flows for salmon migration; protect fish and wildlife habitat and recreational uses when implementing water diversion projects; require that water projects contain safeguards to protect fish and wildlife; design public projects to avoid damage to freshwater and stream environments; require mitigation of impacts on sensitive areas (e.g., riparian habitats, vernal pools, rare plants, flyways, and other waterfowl habitats); restore freshwater habitats.
	Protect and restore natural resources like wetlands and riparian areas; achieve a "no net loss" of wetland areas through avoidance, protection, and appropriate mitigation; protect riparian habitat along rivers and natural waterways; address potential impacts on waterways and wetlands resulting from increased erosion and siltation.

Specific impacts on affected resources addressed in these plans—including water, biological, recreational, and visual resources—resulting from implementation of the WSIP water supply and system operations are analyzed by watershed in the corresponding sections of this chapter.

5.2.4 Plan Consistency Evaluation

The evaluation of plan/policy consistency in this section is based on the applicability of adopted plans and policies to the proposed WSIP water supply and system operations and associated effects. The consistency evaluation in this PEIR represents the best attempt to advise the decision-makers as to whether the proposed program is consistent with applicable *adopted* land use and resource plans and policies. No consistency determination is made for draft plans/policies, plans in development, guidance/planning documents, or agreements. However, the resources addressed in the draft plans/policies or guidance/planning documents are evaluated in the impact analyses in the appropriate sections of this chapter. In general, implementation of the WSIP would be consistent with natural resource and other applicable plans described in Section 5.2.3, particularly with respect to the WSIP sustainability goal of managing natural resources and physical systems to protect watershed ecosystems and with implementation of mitigation measures identified in this PEIR.

Consistency with Regional Natural Resource Protection Plans

WQCPs identify water quality issues and prescribe enforceable water quality objectives/criteria for specific water bodies and their tributaries. Because these standards are based on designated beneficial uses of the respective waterways, violation of the water quality objectives/criteria can adversely affect fish, wildlife, and other protected resources. SFPUC operations currently comply with water quality standards contained in the WQCPs, and the WSIP goals and objectives would be consistent with the applicable WQCPs. The potential impacts of WSIP implementation on water quality in the Tuolumne River watershed, Alameda Creek watershed, Peninsula watershed, and Westside Groundwater Basin are analyzed in Sections 5.3.3, 5.4.3, 5.5.3, and 5.6, respectively.

One adopted HCP covering an area that could be affected by WSIP implementation was identified; this plan was prepared by the City of Waterford for the incidental take of valley elderberry longhorn beetle (VELB) on the Tuolumne River at a location between La Grange Dam and Modesto. The goals and objectives of the WSIP would be consistent with this HCP, and, as described in Section 5.3.7, implementation of the WSIP would not adversely affect the VELB or elderberry population in this plan area.

Consistency with CCSF Plans and Policies

San Francisco General Plan

The San Francisco General Plan provides general environmental resource policies related to the protection of natural resources, including freshwater resources. The WSIP goals and objectives would be consistent with the goals and objectives of this plan, and more specifically with policies related to freshwater resources. The impact analyses presented in Sections 5.3 through 5.7 of this chapter assess the potential for physical environmental impacts from implementation of the WSIP water supply and system operations. The impact analyses identify a variety of potentially significant physical impacts under all environmental topics, but, as described in those sections,

many of these impacts would be reduced to a less-than-significant level with implementation of mitigation measures and compliance with applicable regulations, as outlined in Chapter 6.

San Francisco Sustainability Plan

The *San Francisco Sustainability Plan* was developed for the purpose of addressing San Francisco's long-term environmental sustainability. Water supply goals relevant to the WSIP deal with ensuring a sustainable and adequate water supply; maximizing public health by providing safe drinking water; ensuring public input into the water planning process; restoring and enhancing groundwater supplies; and upgrading infrastructure in a timely and environmentally sound manner. The WSIP water supply and system operations, and particularly the WSIP sustainability objective, would be consistent with the goals of the Sustainability Plan. The WSIP would be consistent with goals pertaining to increasing water reuse, ensuring an adequate water supply under normal and extraordinary conditions, restoring groundwater supplies, and upgrading infrastructure.

San Francisco Urban Water Management Plan

The *2005 Urban Water Management Plan for the City and County of San Francisco* evaluates regional water system reliability and the SFPUC's existing and planned sources of water supply. The plan describes demand management measures to be implemented and provides an implementation strategy and schedule for future planned projects and schedules. Information in the UWMP was used in the development of WSIP levels of service and complements the operational strategy and future water supplies proposed under the WSIP. Therefore, the WSIP is and would be inherently consistent with the UWMP.

Consistency with Adopted SFPUC Plans and Policies

Alameda and Peninsula Watershed Management Plans

Watershed management plans prepared by the SFPUC for the purpose of water resource management and planning provide much of the framework used in the development of various components of the WSIP. The Peninsula and Alameda WMPs are designed to improve the SFPUC's ability to protect its overall watershed as well as the specific resources that make up the watershed. The WMPs include goals and policies related to maximizing the local water supply and improving source water quality to protect public health and safety; these goals are aligned with the goals of the WSIP. As part of implementing the WMPs, the SFPUC Natural Resources Division will review WSIP activities proposed within these watersheds for conformity with the WMPs as well as for compliance with environmental codes and regulations; thus, changes in system operations proposed under the WSIP would be reviewed for conformity with the goals, policies, and management actions contained in the Alameda and Peninsula WMPs. Overall, the WSIP would be consistent with the WMPs. Potential impacts of WSIP system operations on water quality and biological resources in the Alameda and Peninsula watersheds are described in Sections 5.4 and 5.5 of this chapter.

SFPUC Water Enterprise Environmental Stewardship Policy

The WSIP would be consistent with the underlying goals of the Water Enterprise Environmental Stewardship Policy, particularly with respect to the WSIP sustainability goal and the WSIP objective to manage natural resources and physical systems to protect watershed ecosystems. The Stewardship Policy implementation strategy specifically calls for integration of the policy into the WSIP. However, implementation of the proposed water supply and system operations would affect stream flow in the Tuolumne River, Alameda Creek, and Peninsula watersheds, as analyzed and described in Sections 5.3.1, 5.4.1, and 5.5.1. This operational change and resultant effects on stream flow could in turn affect native fish and wildlife downstream of SFPUC dams and water diversions, within SFPUC reservoirs, and on SFPUC watershed lands. Impacts on fisheries and the terrestrial biological resources in the Tuolumne River, Alameda Creek, and Peninsula watersheds are analyzed in Sections 5.3.6, 5.3.7, 5.4.5, 5.4.6, 5.5.5, and 5.5.6. Mitigation measures described in Chapter 6 identify operational approaches to managing releases from SFPUC reservoirs and other measures to reduce impacts on fisheries and other biological resources.

Consistency of WSIP Operations with the General Plans of Potentially Affected Counties

Overall, the WSIP water supply and system operations would be generally consistent with the community goals related to water resources protection described above. Through preparation of this PEIR and attendant scoping and public outreach efforts, the CCSF has systematically identified significant environmental impacts associated with the WSIP as well as feasible measures and alternatives to avoid or substantially lessen such effects. The impact analyses presented in this PEIR reflect the intent of general plan policies related to the protection of water resources. As detailed throughout the rest of Chapter 5, most of the environmental impacts associated with the proposed water supply and system operations would be reduced to a less-than-significant level with measures proposed as part of the WSIP or otherwise committed to by the SFPUC.

5.3 Tuolumne River System and Downstream Water Bodies

Section 5.3 Subsections	
5.3.1	Stream Flow and Reservoir Water Levels
5.3.2	Geomorphology
5.3.3	Surface Water Quality
5.3.4	Surface Water Supplies
5.3.5	Groundwater
5.3.6	Fisheries
5.3.7	Terrestrial Biological Resources
5.3.8	Recreational and Visual Resources
5.3.9	Energy Resources
(References included under each section)	

5.3.1 Stream Flow and Reservoir Water Levels

The following setting section describes the streams and reservoirs in the Tuolumne River watershed and downstream that could be affected by the WSIP. The impact section (Section 5.3.1.2) provides a description of the changes in stream flow and reservoir water levels that would result from implementation of the WSIP.

5.3.1.1 Setting

The Tuolumne River flows from the crest of the Sierra Nevada westward to its confluence with the San Joaquin River. The San Joaquin River flows north to the Sacramento–San Joaquin Delta. Water from the Delta discharges to the San Francisco Bay Estuary and the Pacific Ocean.

Surface water bodies in the Tuolumne River system that could be affected by the proposed program include the Tuolumne River, Cherry Creek, Eleanor Creek, and a quarter-mile reach of Moccasin Creek. Several reservoirs could be affected by the WSIP, including Hetch Hetchy Reservoir, Lake Lloyd, Lake Eleanor, and Don Pedro Reservoir. Because the Tuolumne River drains to the San Joaquin River and the Sacramento–San Joaquin Delta, these water bodies could also be affected by the WSIP. The proposed program could affect flow in the streams and water levels and water quality in the reservoirs.

Tuolumne River

General Description

The Tuolumne River rises in Yosemite National Park and flows approximately 130 miles to its confluence with the San Joaquin River about 10 miles west of the city of Modesto. Its headwaters are streams that descend the slopes of Mount Lyell and Mount Dana in the Sierra Nevada and join

to form the river itself at Tuolumne Meadows. The Tuolumne River drains an area of 1,958 square miles. Its watershed is shown in **Figure 5.3.1-1**.

From Tuolumne Meadows (at an elevation of 8,600 feet above sea level), the river descends rapidly through a deep canyon in wilderness areas of Yosemite National Park to Hetch Hetchy Reservoir (at an elevation of about 3,500 feet). Six miles below O'Shaughnessy Dam, which impounds Hetch Hetchy Reservoir, the Tuolumne River leaves Yosemite National Park and enters the Stanislaus National Forest. Except for a short reach at Early Intake Reservoir, the river flows unimpeded through a deep canyon for approximately 40 miles, from O'Shaughnessy Dam to the upstream end of Don Pedro Reservoir.

Don Pedro Reservoir is at an elevation of about 500 feet. Several tributaries, including Cherry Creek, Jawbone Creek, the Clavey River, the North Fork of the Tuolumne River, and Turnback Creek, join the river from the north between Hetch Hetchy and Don Pedro Reservoirs. The South Fork of the Tuolumne joins the river from the south. Moccasin Creek and Woods Creek drain directly into Don Pedro Reservoir.

Below Don Pedro Reservoir, the Tuolumne River flows 2.3 miles to La Grange Dam, where water is diverted into two irrigation canals. Below La Grange Dam, the Tuolumne River descends through the Sierra Nevada foothills to the floor of the San Joaquin Valley and on to its confluence with the San Joaquin River, which is at an elevation of about 60 feet above sea level. This reach of the river flows through land used primarily for irrigated agriculture. A major tributary, Dry Creek, joins the river from the north in the city of Modesto.

Runoff in the Tuolumne River basin is produced by rainfall and snowmelt. Rainfall runoff occurs primarily in the Sierra foothills and the valley floor between December and March. Runoff from the upper basin is produced by snowmelt and occurs primarily between April and July. Annual runoff in the Tuolumne River basin is highly variable. Average annual "unimpaired" runoff[1] at Don Pedro Reservoir is estimated to be about 1.85 million acre-feet for the period from 1918 to 1991. The maximum estimated value is 3.84 million acre-feet in 1969, and the minimum is 0.39 million acre-feet in 1977 (Beck, 1992).

Stream Flow and Water System Operations

Flow in the Tuolumne River remained unaffected by humans until the 1860s, when water from the lower reaches of the river began to be diverted for agricultural irrigation. In 1871, a private company constructed Wheaton Dam near the site of present-day La Grange Dam. Wheaton Dam was used to divert water into irrigation canals. In 1887, the newly formed Turlock Irrigation District (TID) and Modesto Irrigation District (MID) constructed a new diversion dam, La Grange Dam, to replace Wheaton Dam (TID/MID, 2005).

[1] Unimpaired flow at a point on a river is the flow that would have occurred if there were no upstream water diversions or storage reservoirs. For the Tuolumne River, it is roughly equivalent to "natural flow"; that is, the flow that would have occurred prior to Euro-American settlement.

Figure 5.3.1-1b

Tuolumne River Watershed,
Don Pedro Reservoir to San Joaquin River

Early in the 20th century, development of the Tuolumne River accelerated. In 1918, the City and County of San Francisco (CCSF) completed Lake Eleanor, a reservoir on Eleanor Creek. Eleanor Creek is a tributary of Cherry Creek, which is itself a tributary of the Tuolumne River. Hetch Hetchy Reservoir and the original Don Pedro Reservoir, on the main stem of the river, were completed in 1923 (Hetch Hetchy by the CCSF and Don Pedro Reservoir by TID and MID). Hetch Hetchy Reservoir was expanded in 1938. In 1955, the CCSF completed Lake Lloyd on Cherry Creek. In 1971, TID and MID completed the new Don Pedro Reservoir, a much larger reservoir two miles downstream of the site of the original Don Pedro Reservoir (SFPUC, 2005).

Hetch Hetchy Reservoir, Lake Eleanor, and Lake Lloyd are owned by the CCSF and operated by the SFPUC, and Don Pedro Reservoir is owned and operated by TID and MID. The CCSF paid a portion of the construction costs of Don Pedro Reservoir and in return has indirect access to, and control of, a portion of the storage capacity of the reservoir by means of a water banking arrangement with the districts.[2]

Figure 5.3.1-2 is a diagrammatic representation of the natural features of the Tuolumne River showing the water and hydropower facilities that affect flow in the river. The figure also shows the approximate storage capacity of the reservoirs and the electrical generation capacity of the hydropower facilities.

The SFPUC diverts water from Hetch Hetchy Reservoir in the upper Tuolumne River basin and conveys it to the Bay Area in the Hetch Hetchy Aqueduct. The Hetch Hetchy Aqueduct consists of a series of facilities extending from Hetch Hetchy Reservoir to Crystal Springs Reservoir in San Mateo County (see Figure 2.1 in Chapter 2). Water leaves Hetch Hetchy Reservoir in the Canyon Power Tunnel, which delivers water to Kirkwood Powerhouse at Early Intake. Water leaving the powerhouse is either returned to the Tuolumne River or discharged into the Mountain Tunnel. The Mountain Tunnel conveys water to Priest Reservoir and Moccasin Powerhouse. Water discharged from Moccasin Powerhouse is either returned to the Tuolumne River via Moccasin Reservoir and Moccasin Creek or discharged to the Foothill Tunnel for conveyance to the Bay Area. Priest and Moccasin Reservoirs are small reservoirs used to control flow into Moccasin Powerhouse and regulate discharge of water to Moccasin Creek.

The SFPUC diverts an average of 244,000 acre-feet per year (afy) (218 million gallons per day [mgd]) from the Tuolumne River at Hetch Hetchy Reservoir and uses it for municipal water supply to about 2.4 million people in Tuolumne, Alameda, Santa Clara, San Mateo, and San Francisco Counties. Additional water is diverted at Hetch Hetchy Reservoir for hydropower generation at Kirkwood Powerhouse, but is returned to the Tuolumne River below Early Intake. The water diverted by the SFPUC for water supply represents about 32.5 percent of the average annual unimpaired runoff at Hetch Hetchy Reservoir, which is estimated to be 749,607 acre-feet. **Figure 5.3.1-3** shows the historical record of water storage in Hetch Hetchy Reservoir, as reflected in water levels, from 1989 to 2005.

[2] The SFPUC does not have direct access to its portion of storage in Don Pedro Reservoir. Instead, the SFPUC diverts water at Hetch Hetchy Reservoir by withholding water that TID and MID are entitled to receive under the Raker Act, thereby reducing the SFPUC's storage in Don Pedro Reservoir.

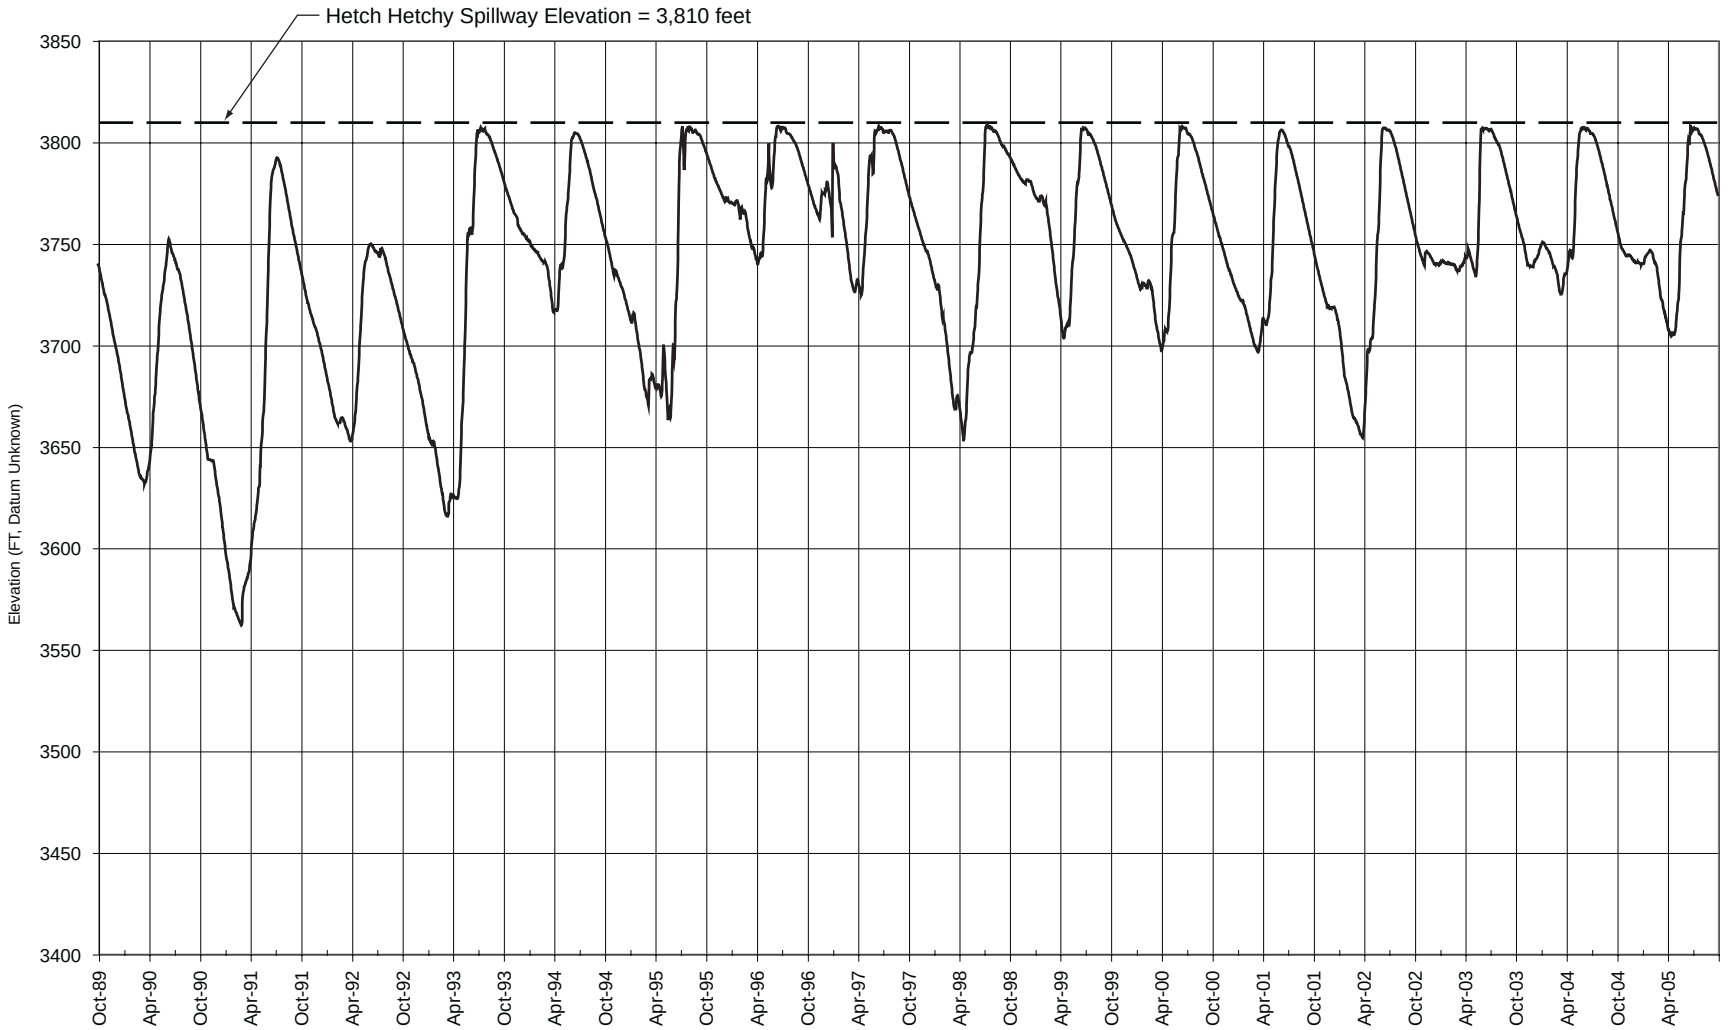
Tuolumne River Schematic
Showing Water and Hydropower Facilities



SOURCE: SFPUC, 2007

Figure 5.3.1-3

Hetch Hetchy Reservoir, Historical Water Levels, 1989 to 2005

The SFPUC uses most of the water impounded in Lake Lloyd to generate electrical power at Holm Powerhouse. Water released from the powerhouse returns to Cherry Creek and is used to satisfy TID's and MID's flow entitlement. Water impounded in Lake Eleanor is conveyed to Lake Lloyd and then to Holm Powerhouse for electric power generation. **Figures 5.3.1-4** and **5.3.1-5** show the historical record of water storage in Lake Lloyd and Lake Eleanor, respectively, as reflected in water levels, from 1989 to 2005.

TID and MID divert water from the Tuolumne River at La Grange Dam. Water is conveyed to users in the two districts' service areas via the Modesto and Turlock Canals. Most of the users of water from the two canals are farmers, but some water is used for municipal supply by the city of Modesto. TID and MID typically divert 800,000 to 900,000 afy from the Tuolumne River. **Figure 5.3.1-6** shows the historical record of water storage in Don Pedro Reservoir, as reflected in water levels, from 1989 to 2005. Average annual unimpaired runoff at La Grange Dam is estimated to be 1,850,000 acre-feet. Thus, TID and MID currently divert 49.6 percent of the estimated average unimpaired flow of the Tuolumne River at La Grange. Together, the SFPUC, TID, and MID divert and use about 62.8 percent of the estimated average unimpaired flow of the Tuolumne River at La Grange.

Table 5.3.1-1 shows monthly average flows in the Tuolumne River below Hetch Hetchy Reservoir, below La Grange Dam, and at Modesto under current conditions, calculated from stream gaging records. Monthly average flows below Hetch Hetchy Reservoir range from 382 to 2,293 cubic feet per second (cfs) and peak in the late spring and early summer as the snow in the Sierra Nevada melts. Monthly average flows in the Tuolumne River below La Grange range from 243 to 1,884 cfs. Monthly average flows in the river at Modesto range from 431 to 2,236 cfs. Monthly average flows below La Grange and at Modesto peak in the late winter and early spring as a result of rainfall runoff and releases from Don Pedro Reservoir. Water may be released from Don Pedro Reservoir in the late winter and spring to provide capacity in the reservoir for floodwaters and snowmelt.

Reservoirs and diversions have altered the magnitude and seasonal patterns of flow in the Tuolumne River. Prior to construction of the reservoirs, the river experienced large and sustained flows in the spring as snow melted at higher elevations in the watershed. Now a portion of the spring flows is stored in the reservoirs for later municipal or agricultural use. Peak flows below reservoirs, particularly the large Don Pedro Reservoir, are greatly reduced from their historical value. The two-year return-period flood flow in the Tuolumne River downstream of La Grange Dam is 4,100 cfs; its predevelopment value was 21,000 cfs. The 20-year return-period flood flow on the Tuolumne River downstream of La Grange Dam is 11,000 cfs; its predevelopment value was 59,000 cfs (FERC, 1996).

As discussed below, various regulations and agreements require that reservoir operators maintain minimum flows in the Tuolumne River and its tributaries downstream of dams. During the late summer and early fall, the required minimum flows may be greater than those that occurred prior to development.

Minimum Releases to Support Fisheries

Dams and reservoirs alter the pattern of flow in the streams they impound. Depending on their size and type of use, these facilities can completely eliminate flow in the streams below the dams. The owners of some dams and reservoirs, including the SFPUC, MID, and TID, have agreed to make minimum releases to stream channels below dams to support fish and aquatic life.

Below Hetch Hetchy Reservoir. In accordance with an agreement with the U.S. Department of the Interior, the SFPUC releases a minimum stream flow from Hetch Hetchy Reservoir.[3] Minimum flow requirements depend on the hydrologic year type and are shown in **Table 5.3.1-2**. Releases in normal, dry, and critical years total at least 59,235, 50,019, and 35,215 acre-feet. The SFPUC must release an additional 64 cfs into the river below Hetch Hetchy Reservoir when the diversion through Canyon Tunnel exceeds 920 cfs. Finally, the agreement provides for an additional supplemental release, depending on hydrologic year type, subject to the completion of a fish habitat study and the determination of appropriate timing for the release. Once made, releases cannot be diverted below O'Shaughnessy Dam (i.e., at Early Intake); they flow down the Tuolumne River, are supplemented by tributary flow and releases at Kirkwood Powerhouse, and enter Don Pedro Reservoir.

[3] Stipulation for the Amendment of Rights-of-Way for Canyon Power Project Approved by Secretary of the Interior on May 26, 1961, to fulfill the conditions set forth in Provision 6 of said Amended Permit, dated January 31, 1985, *as modified by*, Modification for Kirkwood Powerhouse Unit No.3 to Stipulation for Amendment of Rights-of-Way for Canyon Power Project Approved by Secretary of the Interior on May 26, 1961, to fulfill the conditions set forth in Provision 6 of said Amended Permit, as dated March 10, 1987.

TABLE 5.3.1-2
SCHEDULE OF AVERAGE DAILY MINIMUM REQUIRED RELEASES TO SUPPORT FISHERIES BELOW O'SHAUGHNESSY DAM

Month	Year Type A		Year Type B		Year Type C
	Release	Criteria[a,b]	Release	Criteria[a,b]	Release
January	50 cfs	8.80 inches	40 cfs	6.10 inches	35 cfs
February	60 cfs	14.00 inches	50 cfs	9.50 inches	35 cfs

November	60 cfs		50 cfs		35 cfs
December	50 cfs		40 cfs		35 cfs

[a] Precipitation indicators in inches are cumulative, measured at Hetch Hetchy Reservoir, starting October 1. For example, if October 1 through December 31 precipitation is greater than or equal to 8.80 inches, refer to year type A schedule for January.
[b] Runoff indicators in acre-feet are the calculated inflow into Hetch Hetchy Reservoir commencing on the previous October 1 of each year.

SOURCE: See Footnote 3, page 5.3.1-12.

Below Lake Lloyd. The minimum required stream flow below Lake Lloyd is 5 cfs from October through June and 15 cfs from July through September.

Below Lake Eleanor. In years when no pumping occurs between Lake Eleanor and Lake Lloyd, the minimum required stream flow below Lake Eleanor is 5 cfs from October through June and 15.5 cfs from July through September. In years when pumping occurs, the minimum required stream flow is 5 cfs from November through February, 10 cfs from March 1 through April 14, 20 cfs from April 15 through September 15, and 10 cfs from September 16 through October.

Below Don Pedro Reservoir/La Grange Dam. TID and MID are required to maintain minimum stream flows in the Tuolumne River at La Grange Bridge below Don Pedro Reservoir and La Grange Dam as a condition of their license to operate the Don Pedro Project (issued by the Federal Energy Regulatory Commission, or FERC). Minimum required releases are 100 to 300 cfs from October 1 to 15 and 150 to 300 cfs from October 16 to May 31, depending on hydrologic conditions. From June 1 to September 30, the minimum required releases range from 50 to 250 cfs depending on hydrologic conditions. Additional pulse releases must be made to assist upstream migrating adult Chinook salmon and downstream migrating juveniles. Minimum annual releases from La Grange Dam, including the pulse releases, vary from at least 94,000 acre-feet in critically dry years to approximately 300,000 acre-feet in above-normal and wet years. A detailed minimum stream flow schedule is shown in **Table 5.3.1-3**.

San Joaquin River

General Description

The San Joaquin River rises in the Sierra Nevada west of Mammoth Lakes and drains an area of approximately 13,500 square miles. The river flows southwestward, through the Sierra foothills, to the floor of the San Joaquin Valley near the city of Fresno. After reaching the valley floor, it turns and flows northwest for about 100 miles to the Sacramento–San Joaquin Delta. Several major tributaries join the San Joaquin River from the east, including the Fresno, Chowchilla, Merced, Tuolumne, and Stanislaus Rivers. The San Joaquin River watershed is shown in **Figure 5.3.1-7**.

Stream Flow and Water System Operations

Flow in the San Joaquin River is controlled by releases from Millerton Lake on the main stem of the river and from several reservoirs on the San Joaquin's tributaries. Millerton Lake is part of the federal Central Valley Project. It is impounded by Friant Dam, which was completed in 1942. The Central Valley Project's Friant-Kern and Madera Canals convey most of the runoff from the San Joaquin River drainage above Millerton Reservoir to agricultural and urban water users. The U.S. Bureau of Reclamation (USBR) releases enough water at Friant Dam to maintain a flow of 5 cfs past Gravelly Ford, which is 35 miles below the dam, to meet downstream riparian water rights. The reach of the river between Gravelly Ford and Mendota is essentially dry, except when flood releases are being made. In the future, flow will be restored in the San Joaquin River between Friant Dam and the confluence with the Merced River in accordance with a recent settlement agreement between the USBR and an environmental advocacy organization, the Natural Resources Defense Council.

SFPUC Water System Improvement Program . 203287

Figure 5.3.1-7

San Joaquin River Watershed

The San Joaquin River gains water as it flows toward the Sacramento–San Joaquin Delta from agricultural irrigation return flows and tributaries. Flow in the San Joaquin River at Newman upstream of the river's confluence with the Tuolumne River averaged 1,789 cfs based on stream flow gaging records for the period between 1942 and 2004. Flow in the San Joaquin River at Vernalis, upstream of the Delta and downstream of the Tuolumne River confluence, averaged 4,328 cfs based on stream flow gaging records for the period between 1942 and 2004. Mean monthly stream flows at Newman and Vernalis are shown in Table 5.3.1-1. The highest flows occur in February, March, April, and May and the lowest in August and September. A substantial proportion of the increase in San Joaquin River flow between Newman and Vernalis is contributed by the Tuolumne River, which has an average annual flow of 1,265 cfs as measured at Modesto.

Sacramento–San Joaquin Delta

General Description

The Sacramento–San Joaquin Delta is a 600-square-mile area of channels and islands at the confluence of the Sacramento and San Joaquin Rivers. Freshwater draining from a 41,300-square-mile watershed enters the Delta from the Sacramento and San Joaquin Rivers and several smaller rivers. Some of the freshwater is diverted from the Delta channels for municipal and agricultural purposes. The remainder flows through the Delta to the San Francisco Bay Estuary.

The Delta is a tidal region. Every 12.4 hours, the tides cause water to move in and out of the Delta. Most of the time, tides cause a five- to eight-mile back and forth movement of water in the western part of the Delta. The average tidal flow into the Delta on the flood tide and out of the Delta on the ebb tide is 170,000 cfs (Miller, 1993). The movement of freshwater through the Delta is superimposed on the tidal flows. Typical freshwater flows are much smaller than tidal flows, usually in the range of 5 to 15 percent of the tidal flows.

Stream Flow and Water System Operations

On average, about 21 million acre-feet of water reaches the Delta annually, but actual inflow varies widely from year to year and within the year. In 1977, a year of extraordinary drought, Delta inflow totaled 5.9 million acre-feet. In 1983, an exceptionally wet year, Delta inflow was about 70 million acre-feet. On a seasonal basis, average monthly flow into the Delta varies by more than a factor of 10 between the highest month in the winter or spring and the lowest month in the fall (SWRCB, 1997).

The Sacramento River, which enters the Delta from the north, contributes an average of 77 percent of the inflow to the Delta. The San Joaquin River, which enters the Delta from the south, contributes about 15 percent of the inflow. The remainder is contributed by the Mokelumne, Cosumnes, and Calaveras Rivers, which enter the Delta from the east (DWR, 1998).

Most of the Delta islands are used to grow crops. Delta farmers divert water directly from the Delta channels to irrigate their land. A portion of the diverted water is returned to the Delta channels as agricultural return. The average annual net diversion of water for irrigation within the Delta is estimated to be 960,000 acre-feet (San Francisco Estuarine Project, 1992).

California's two largest engineered water systems, the Central Valley Project and the State Water Project, also divert water from the Delta. The Central Valley Project diverts water from Old River in the south Delta at the Jones Pumping Plant (formerly Tracy Pumping Plant) and exports it to Central Valley Project contractors via the Delta-Mendota Canal. Contra Costa Water District, a Central Valley Project contractor, diverts its water from Old River and Rock Slough in the south Delta and Mallard Slough in the west Delta. The State Water Project diverts water from Old River at the Banks Pumping Plant and exports it to customers via the California Aqueduct, the South Bay Aqueduct, and the Central Coast Aqueduct. The State Water Project diverts smaller amounts of water from Barker Slough in the north Delta to serve customers in Napa and Solano Counties. Between 1995 and 2004, the State Water Project diverted an average of 2.4 million afy from the Delta. The Central Valley Project diverts an average of 1.7 million afy from the Delta.

Delta freshwater outflow, commonly referred to simply as Delta outflow, is roughly equal to Delta inflow minus net water diversions in the Delta for use in the Delta and diversions for export. Like Delta inflow, Delta outflow varies widely from month to month and from year to year. Between 1984 and 2004, Delta outflow averaged 16.9 million acre-feet. The greatest annual Delta outflow in the period was 43.5 million acre-feet in 1998. The smallest Delta outflow in the period was 3.9 million acre-feet in 1990 (DWR, 2007). Average monthly Delta outflow for the same period is shown in Table 5.3.1-1. The largest Delta outflow typically occurs in January, February, and March, when surface runoff is high and demand for irrigation water is low. The smallest Delta outflow typically occurs in July, August, September, and October.

The diversion of water by the Central Valley Project, State Water Project, and others in the south Delta as well as upstream depletion of San Joaquin River flows affect the pattern of flow in the Delta channels. Historically, net flow in the Delta channels was toward the San Francisco Bay Estuary. Now, because freshwater inflow to the south Delta from the San Joaquin River is small relative to the diversions at the Banks and Tracy Pumping Plants, net flow in many south Delta channels reverses during summer and fall. Flow in the lower San Joaquin River and the south Delta channels is directed upstream toward the pumping plants rather than downstream toward the estuary (Miller, 1993).

The diminution of flow and flow reversals in the lower San Joaquin River as a result of water diversions by the State Water Project and Central Valley Project are harmful to migrating salmon. In 1990, the California Department of Water Resources (DWR) began installing temporary barriers in several waterways in the south Delta to improve conditions for migrating salmon. Temporary barriers have been placed across the Grant Line Canal, Middle River, and Old River. The purpose of the barriers is to control water levels for irrigators, improve water quality, and direct more water down the lower San Joaquin River for downstream migrating juvenile salmon in the spring and upstream migrating adults in the fall. It is expected that permanent operable barriers will replace the temporary barriers in the future years.

Flow Objectives for the Sacramento–San Joaquin Delta

As noted above, the Sacramento–San Joaquin Delta lies at the heart of California's natural and manmade water systems. The Delta's physical complexity and competing interests for water make management of the Delta difficult. Since water quality objectives alone are insufficient to protect the Delta, regulators have also established objectives for flow. These objectives have been the subject of much controversy and have frequently been revised. Some issues remain unresolved, including the degree to which parties that divert water upstream of the Delta are responsible for meeting Delta objectives. Resolution of these issues could affect all upstream diverters, including the SFPUC, TID, and MID.

The State Water Resources Control Board (SWRCB) is the agency responsible both for setting water quality objectives for the Delta and for issuing and administering water-rights permits in California. The degree to which parties that divert water upstream of the Delta are responsible for maintenance of Delta water quality and flow objectives may ultimately be resolved through a water-rights proceeding.

Water-Rights Decisions

In 1997, the SWRCB began examining long-term alternatives that would enable compliance with the flow objectives for the Delta. Water rights proceedings to determine responsibility for meeting the flow objectives began in 1998 (see Section 5.3.3 for more detail). The water-rights proceedings were to be conducted in eight phases. The SWRCB's policy in the water-rights proceedings was to encourage water agencies to resolve among themselves the responsibilities for meeting the objectives in the 1995 Water Quality Control Plan (WQCP) and to bring their proposals to the SWRCB for approval. In 1999, the SWRCB published a final EIR on the WQCP, which presented the environmental effects of a range of alternatives but did not identify a preferred alternative (SWRCB, 1999).

In late 1999, following Phases 1 through 7 of the Bay-Delta water rights proceedings, the SWRCB issued Water Rights Decision 1641. The SWRCB revised D-1641 in early 2000 by issuing Order WR 2000-02, and again in 2001 by issuing Order WR 2001-05. D-1641 and Order WR 2001-05 contain the water-right requirements to implement the flow objectives for the Delta. D-1641 includes both long-term and temporary requirements that will remain in effect for up to 35 years. Order WR 2001-05 called for partial implementation of the requirements.

In D-1641 and Order WR 2001-05, the SWRCB assigned responsibilities to water-rights holders for specified periods, including the USBR and DWR, in certain watersheds tributary to the Delta. The SWRCB accepted with modifications the proposals made by some water agencies and groups of water agencies with respect to their responsibilities for meeting flow objectives in the Delta. The responsibilities of various parties, including water users in the Sacramento, San Joaquin, Mokelumne, Calaveras, and Cosumnes River watersheds, were defined in D-1641. These responsibilities require that the water users in these watersheds contribute specified amounts of water to protect water quality or implement agreements (including the San Joaquin River Agreement, as described below), and that the USBR and/or DWR ensure the objectives are met in the Delta.

Phase 8 of the water-rights proceedings would have ultimately determined the responsibilities of the Sacramento Valley water-rights holders for meeting the objectives in the 1995 WQCP. The SWRCB's Order WR 2001-05 stayed Phase 8 of the proceedings and required the USBR and DWR to continue to meet certain objectives in the 1995 WQCP until adoption of another decision assigning responsibility for meeting the objectives. During 2002, the USBR, DWR, Sacramento Valley upstream water users, and certain downstream users negotiated a settlement in lieu of continuing Phase 8 of the water-rights proceedings. Beginning in December 2002, the parties to the negotiations executed the Sacramento Valley Water Management Agreement, or Short Term Settlement Agreement. The agreement establishes a planning process for actions that would help meet objectives in the Delta.

Vernalis Adaptive Management Program

Shortly after the Bay-Delta WQCP was published, an association of users of San Joaquin River water filed suit against the SWRCB, challenging the flow objectives in the WQCP. The association claimed that the flow objectives were based on an inadequate understanding of the relationship between flow and salmon survival. In an effort to settle the issue out of court, the San Joaquin River interests collaborated with other water users, environmental groups, and government agencies to develop an alternative that would provide an equivalent level of fishery protection to that provided by the Bay-Delta WQCP. The result was the San Joaquin River Agreement, of which the Vernalis Adaptive Management Program (VAMP) was a key component (San Joaquin River Group Authority, 2007).

The VAMP is an experimental management program designed to protect juvenile Chinook salmon migrating from the San Joaquin River through the Delta. The San Joaquin River Agreement, including the VAMP, was submitted to the SWRCB as a proposal. It was accepted by the SWRCB and made a part of D-1641. In February 2006, however, the Third Appellate District overturned that part of D-1641 and ordered to SWRCB to commence further proceedings to either assign responsibility for meeting the Vernalis pulse-flow objectives in full or to modify those objectives. In December 2006, the SWRCB adopted amendments to the 1995 Bay-Delta WQCP, including allowing for staged implementation through the San Joaquin River Agreement until December 2011.

The VAMP provides for a 31-day pulse flow in the San Joaquin River at Vernalis, together with a reduction in State Water Project and Central Valley Project exports from the south Delta. The pulse usually occurs from mid-April to mid-May, but its timing may be adjusted based on hydrology and fishery conditions. The effects of different flow rates in the lower San Joaquin River and different State Water Project and Central Valley Project export rates on juvenile and smolt Chinook salmon survival are being studied as part of the VAMP. The VAMP is scheduled to end in 2011.

5.3.1.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to stream flow and reservoir water levels, but generally considers that implementation of the proposed program would have a significant impact if it were to:

- Substantially alter stream flows such that they are outside of the range of pre-project conditions and result in adverse hydrologic effects

The stream flow significance threshold is based on the fact that natural stream flows and controlled reservoir levels have varied substantially in the past 50 years, and such variations are a part of the existing baseline. Therefore, variations substantially outside of these past levels due to implementation of the proposed program that would result in an adverse hydrologic effect (such as flooding, dewatering, drainage alteration, or erosion, among others) would be considered a significant direct impact.

This PEIR also considers indirect impacts due to changes in stream flows and reservoir levels. However, for organizational purposes, the indirect impacts are not described in this section of this chapter, but rather in the sections describing the resources that would be indirectly affected by changes in flows and reservoir levels. These include geomorphology, surface water quality, surface water supplies, groundwater, fisheries, terrestrial biological resources, and recreational and visual resources. It should be noted that there might be cases where significant indirect impacts could result from less-than-significant direct flow impacts.

Approach to Analysis

Changes in flow in rivers and streams and changes in reservoir storage and water levels attributable to the WSIP were estimated using the Hetch Hetchy/Local Simulation Model (HH/LSM). An overview of the model is presented in Section 5.1. The HH/LSM simulates water deliveries, reservoir storage, and releases to rivers under different conditions using hydrologic data from the 82-year period 1920 to 2002. Detailed information on the model and the assumptions that underlie it is provided in Appendix H.

The following section addresses the impacts of the WSIP on water levels in Hetchy Hetchy and Don Pedro Reservoirs and flow along the Tuolumne River. WSIP impacts on flow along the San Joaquin River and Sacramento-San Joaquin Delta are also described. In applying the above significance criteria, very infrequent changes in reservoir levels and/or flow are not generally considered to generate a significant effect.

Impact Summary

Table 5.3.1-4 presents a summary of the impacts on stream flow and reservoir levels in the Tuolumne River system and downstream water bodies that could result from implementation of the proposed water supply and system operations.

TABLE 5.3.1-4
SUMMARY OF IMPACTS – STREAM FLOW IN THE TUOLUMNE RIVER SYSTEM AND DOWNSTREAM WATERBODIES

Impact	Significance Determination
Impact 5.3.1-1: Effects on flow along the Tuolumne River below O'Shaughnessy Dam	LS
Impact 5.3.1-2: Effects on flow along Cherry Creek below Cherry Dam	LS
Impact 5.3.1-3: Effects on flow along Eleanor Creek below Eleanor Dam	LS
Impact 5.3.1-4: Effects on flow along the Tuolumne River below La Grange Dam	LS
Impact 5.3.1-5: Effects on flow along the San Joaquin River and the Sacramento–San Joaquin Delta	LS

LS = Less than Significant impact, no mitigation required

Impact Discussion

Impact 5.3.1-1: Effects on flow along the Tuolumne River below O'Shaughnessy Dam.

Reservoir Operations

Hetch Hetchy Reservoir stores water from the upper reaches of the Tuolumne River within Yosemite National Park. During the snowmelt season the reservoir is filled. During the rest of the year, when flow into the reservoir is reduced, the reservoir is drawn down to meet water demand in the service areas of the SFPUC and its customers, instream flow release requirements, and, if necessary, TID's and MID's Raker Act entitlements. Most years, the SFPUC is able to completely refill the reservoir during the snowmelt season. One of the SFPUC's operating goals is to fill the reservoir by the end of June. The WSIP would not change this or any of the SFPUC's other operational goals for Hetch Hetchy Reservoir, but it would affect water levels in the reservoir and the magnitude and timing of releases to the Tuolumne River.

Water Storage and Water Levels in Hetch Hetchy Reservoir

The WSIP would reduce average monthly storage in Hetch Hetchy Reservoir compared to the existing condition. **Figure 5.3.1-8** shows average monthly storage and the range of monthly storage in the reservoir with the WSIP and under existing conditions. The decrease in storage is primarily attributable to increased water demand in the service areas of the SFPUC and its customers. As demand increases, so would diversions of water from Hetch Hetchy Reservoir to supply the SFPUC's customers. Because of the decrease in storage in Hetch Hetchy Reservoir with the WSIP, monthly average water levels would fall by 1 to 10 feet compared to the existing condition.

Figure 5.3.1-9 shows modeled chronological storage in Hetch Hetchy Reservoir and releases to the Tuolumne River using hydrology from the 82-year period 1920 to 2002. The figure compares the WSIP 2030 condition to the existing condition. It shows that, under the existing condition, the SFPUC normally fills Hetch Hetchy Reservoir in the spring and early summer and draws from

Figure 5.3.1-9
Hetch Hetchy Storage and Releases to the Tuolumne River

storage to meet water demand in the summer, fall, and winter. In the early spring, the SFPUC may additionally draw water from the reservoir for power generation, provided it is confident that the coming snowmelt will fill the reservoir.

In the future with the WSIP, the SFPUC would continue to fill the reservoir in the spring and early summer and draw it down during the rest of the year, but the magnitude of the drawdown would be greater than under the existing condition. The reductions in storage and the lowering of water levels attributable to the WSIP would be the greatest in dry years. In average dry years, Hetch Hetchy Reservoir would be drawn down 18 feet more in March (just before refilling begins) than under the existing condition. The WSIP would lower water levels in Hetch Hetchy Reservoir in some months of severe droughts by up to 64 feet compared to the existing condition.

Beginning in July, when the reservoir is usually full, the rate of drawdown with the WSIP would be greater than under the existing condition. As shown in Figure 5.3.1-8, the difference in storage between the two scenarios would increase steadily through the summer, fall, and winter in most years. The pattern would be altered every five years when, with the WSIP, the SFPUC would take a portion of the conveyance system between Hetch Hetchy Reservoir and the Bay Area out of service so it can be maintained. During maintenance, water demand in the Bay Area would be met from local reservoirs, and drawdown of Hetch Hetchy Reservoir would cease for several weeks. On completion of maintenance, drawdown of Hetch Hetchy Reservoir would recommence at an accelerated rate as water is moved to storage in the local reservoirs. The WSIP would not alter water levels in Hetch Hetchy Reservoir such that they would be substantially outside the range experienced under the existing condition. Under the existing condition and in almost all years, the reservoir fills to its maximum capacity of 360,400 acre-feet in the spring and early summer and then is drawn down through the rest of the year. Maximum storage corresponds with a water surface level of 3,806 feet above mean sea level. Only rarely does storage in the reservoir decline below 150,000 acre-feet. A storage capacity of 150,000 acre-feet corresponds with a water surface level of 3,684 feet above mean sea level. Thus, under the existing condition and almost all of the time, the water level fluctuates between 3,806 feet and 3,684 feet, a range of 122 feet. With the WSIP, the water level in Hetch Hetchy Reservoir would fluctuate within the same range almost all of the time.

Occasionally in extended droughts, storage in Hetch Hetchy Reservoir would be drawn down severely. Under the existing condition, the water level in the reservoir would be drawn down to 3,573 feet, or 233 feet below the maximum, once in the 82-year hydrologic record. With the WSIP, the water level would be drawn down to 3,562 feet, or 244 feet below the maximum, once in the hydrologic record. Thus, water levels with the WSIP would remain substantially within the same range as occurs under the existing condition, although very infrequently water levels would decline slightly below the lower end of the range.

Flow in the Tuolumne River Between O'Shaugnessy Dam and Early Intake

Figure 5.3.1-9 shows the frequency and magnitude of modeled chronological releases from Hetch Hetchy Reservoir to the Tuolumne River under the existing condition and with the WSIP. Under the existing condition, releases to the Tuolumne River are at least equal to the required releases to

support fisheries shown in Table 5.3.1-2. In many years, the volume of spring snowmelt from the watershed upstream of Hetch Hetchy Reservoir exceeds the capacity of the reservoir and the SFPUC's ability to divert water through Canyon Tunnel. Water that cannot be stored or diverted through Canyon Tunnel is released to the Tuolumne River. Occasionally, during the winter, the SFPUC will release excess inflow produced by warm storms to the Tuolumne River.

In the future with the WSIP, the SFPUC would draw the reservoir down farther in most years than it would under the existing condition. Consequently, with the WSIP, the SFPUC would capture a greater proportion of spring runoff to refill the reservoir. As a result, the volume of water released to the Tuolumne River would be reduced compared to the existing condition.

This circumstance is illustrated by the hydrology that occurred in 1991 and 1992. As shown in Figure 5.3.1-9, by the end of the 1991 conditions, Hetch Hetchy Reservoir would be drawn down to a lower level after WSIP implementation than it would under the existing condition. To refill the reservoir in the fairly dry spring of 1992, the SFPUC would have to capture a larger portion of the spring runoff, with the consequence that releases from the reservoir and flow in the Tuolumne River below the reservoir would be reduced, as indicated in the figure.

Table 5.3.1-5 shows average monthly flows in the Tuolumne River immediately below Hetch Hetchy Reservoir in different hydrologic year types for the existing condition and after WSIP implementation. The percentage change in average monthly flow attributable to the WSIP is also shown in the table. The WSIP would have little or no effect on average monthly flow in most summer, fall, and winter months in all hydrologic year types. In most summer, fall, and winter months, only the required fishery release would be made under the existing condition and with the WSIP. With the WSIP, the number of months in which only the required fishery release would be made would increase slightly. Under the existing condition, the model indicates that the minimum release would be made 84.2 percent of the time (837 months in the 987-month hydrologic record); with the WSIP the minimum release would be made 85.4 percent of the time (843 months in the 987-month hydrologic record).

The WSIP would result in reductions in average monthly flow of up to 30 percent in April, May, and June when the SFPUC fills Hetch Hetchy Reservoir with snowmelt. The greatest percentage reduction in flow would occur in normal, below-normal, and dry years because, in these year types, a greater proportion of the snowmelt currently released to the river would be needed to fill the reservoir. For example, in May of an average dry year, flow in the Tuolumne River below O'Shaughnessy Dam would be 224 cfs under the existing condition; with the WSIP it would be 157 cfs, a reduction of 30 percent.

In individual months in the 82-year hydrologic simulation, the absolute and percentage changes in flow in the Tuolumne River below O'Shaughnessy Dam attributable to the WSIP vary widely. The chronological analysis shows that the maximum percentage reduction in average monthly flow would be 80 to 90 percent, occurring three times in the 82-year hydrologic simulation. For example, under the existing condition, May 1992 flow would be 520 cfs; with the WSIP it would be 50 cfs. Reductions in average monthly flow of 30 percent or more would occur in some months of 20 springs in the 82-year simulation, or about once in every four springs on average.

SOURCE: SFPUC, HH/LSM (see Appendix H).

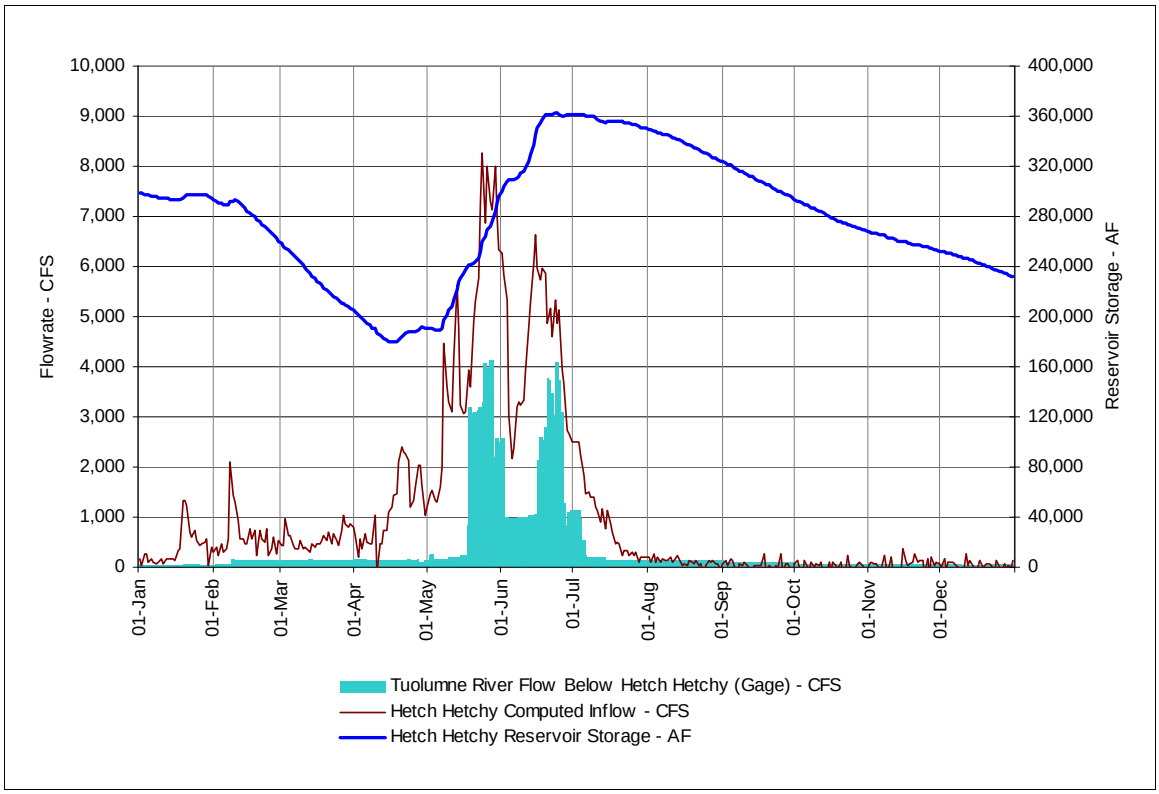
The results presented above are described in terms of average monthly flows because the HH/LSM is a monthly time-step model. The SFPUC's actual operational decisions may occur in smaller time increments, perhaps daily or weekly, depending on meteorological and operational circumstances. For example, if inflow to Hetch Hetchy Reservoir increases rapidly, operators may decide to adjust the rate at which water is routed to Canyon Tunnel or released to the river several times within a month. These within-month operational changes cannot be simulated with the HH/LSM, nor can the model be used to estimate the effects of the WSIP on peak flows in the river, because the peaks may only last for a few hours or days.

Insight into the effects of the WSIP on peak flows below O'Shaughnessy Dam can be obtained by examination of operational data. **Figure 5.3.1-10** shows actual data for 1999, an above-normal year; the greatest effects on peak flows would occur in wet and above-normal years. The figure shows storage in Hetch Hetchy Reservoir falling in the first four months of the year because the rate of withdrawal from the reservoir exceeds the rate of inflow into the reservoir. In April, inflow into the reservoir increases and continues to do so through May. In June, inflow into the reservoir decreases from its peak but remains considerable. Storage in the reservoir increases from its minimum value of about 190,000 acre-feet in mid-April to its maximum value of 360,000 acre-feet in mid-June. The SFPUC reacted to increasing reservoir inflow and diminishing reservoir storage around the middle of May by increasing releases to the Tuolumne River. Measured flow in the Tuolumne River below O'Shaughnessy Dam shows a number of step increases and decreases in flow during May and June lasting several days, as operators balanced reservoir inflow, gains in storage, and releases to the river in response to changing conditions.

If the WSIP had been in place in 1999, and water demand was at 2030 levels, storage in mid-April in Hetch Hetchy Reservoir would have been about 175,000 acre-feet. With the WSIP, operators would need to capture 185,000 acre-feet of runoff to fill the reservoir. Under the existing condition, the operators had to capture 160,000 acre-feet. Needing to capture a higher proportion of runoff with the WSIP than under the existing condition, operators would likely delay releases of water to the Tuolumne River by two to three days. After the initial delay, the releases to the river with the WSIP would follow the same pattern as under the existing condition and would be of a similar magnitude.

The pattern and magnitude of releases from Hetch Hetchy Reservoir to the Tuolumne River with the WSIP in any particular year would depend on meteorological and operational circumstances, as they do under the existing condition. Under the existing condition, there would be no releases from the reservoir to the river in excess of the minimum required release in 15 years of the 82-year hydrologic record. With the WSIP, there would be no releases above the minimum required in 18 years of the 82-year hydrologic record. In years when a release above the minimum required is made, the WSIP would delay the release of water and reduce the total volume of releases to the river in the snowmelt period compared to the existing condition. The WSIP would delay the release of water in excess of minimum requirements by an average of one to two days and could delay the release by up to eight days.[4] The infrequent large peak flows (greater than

[4] The estimates of delay in spring releases are based on the assumption that operators would release water from Hetch Hetchy Reservoir at a rate of 3,000 cfs. A review of past practice indicates that this springtime release rate is typical. If the release rate were to be reduced, as might happen in a dry year, the delay would be extended.



SFPUC Water System Improvement Program ▪ 203287

SOURCE: SFPUC, HH/LSM (see Appendix H).

Figure 5.3.1-10
Hetch Hetchy Reservoir Storage and Inflow,
Calendar Year 1999

5,000 cfs) in the river below O'Shaughnessy Dam produced by rapidly melting abundant snowpack would not be affected by the WSIP. Peak flows in years when runoff is less (dry years) might be reduced by the WSIP, depending on decisions made by reservoir operators.

Impact Conclusions

The WSIP would not alter stream flow in the Tuolumne River below O'Shaughnessy Dam such that it would be substantially outside the range experienced under the existing condition, nor would the flow alterations result in adverse hydrologic effects or be sufficient to change the character of the river. Large, infrequent peak flows under the existing condition and with the WSIP would be similar in magnitude. Minimum flows are the subject of an agreement with the U.S. Department of the Interior and would be the same with the WSIP as under the existing condition. The Department of the Interior could increase the minimum flows in the future based on the fish habitat study referred to above. Overall, the effects of the WSIP on flow along the Tuolumne River below O'Shaughnessy Dam would be *less than significant*, and no mitigation measures would be required.

Impact 5.3.1-2: Effects on flow along Cherry Creek below Cherry Dam.

Reservoir Operations

Lake Lloyd stores water from the upper reaches of Cherry Creek. During the snowmelt season the reservoir is filled. During the rest of the year, when flow into the lake is reduced, the reservoir is drawn down to generate hydroelectric power at the Holm Powerhouse. The releases, which are sized and timed for power generation purposes, also provide opportunities for river rafting and contribute to the releases that the SFPUC must make to satisfy TID's and MID's flow entitlements. Most years, the SFPUC is able to completely refill the lake during the snowmelt season. The WSIP would not change the SFPUC's operational goals for Lake Lloyd, and it would have little or no effect on water levels in the lake and the magnitude and timing of releases to Cherry Creek.

Water Storage and Water Levels in Lake Lloyd

The WSIP would not alter water levels in Lake Lloyd such that they would be substantially outside the range experienced under the existing condition. The WSIP would reduce year-round average monthly storage in Lake Lloyd by about 1,000 acre-feet and average monthly water levels by about 1 foot. Most of the time, storage in Lake Lloyd would be the same with the WSIP as under the existing condition. Infrequent reductions in storage attributable to the WSIP would occur at the end of dry periods, similar to the period that occurred between 1987 and 1992. At the end of dry periods, the SFPUC might release additional water from Lake Lloyd to offset the WSIP-induced reduction in releases from Hetch Hetchy Reservoir. The releases would be needed to satisfy TID's and MID's flow entitlements.

Flow in Cherry Creek

Releases from Lake Lloyd with the WSIP and under the existing condition would be the same and would be at least equal to the fishery release schedule. Thus, the WSIP would have no effect on flow in Cherry Creek.

Impact Conclusions

The WSIP would not alter releases from Lake Lloyd to Cherry Creek. Adverse impacts on flow in Cherry Creek would be *less than significant,* and no mitigation measures would be required.

Impact 5.3.1-3: Effects on flow along Eleanor Creek below Eleanor Dam.

Reservoir Operations

Lake Eleanor stores water from the upper reaches of Eleanor Creek; it fills in the winter and spring of each year and is drawn down in the summer as water is transferred to the lake. The WSIP would not change the SFPUC's operational goals for Lake Eleanor, and it would have little effect on water levels in the lake and the magnitude and timing of releases to Eleanor Creek.

Water Storage and Water Levels in Lake Eleanor

The WSIP would have essentially no effect on monthly storage or water levels in Lake Eleanor compared to the existing condition. The only change in modeled chronological storage using hydrology from the period 1920 to 2002 occurs during the last year of the 1987–1992 drought. Under 2002 conditions with the WSIP, additional water would be transferred from Lake Eleanor to supplement storage in Lake Lloyd. Such a transfer would occur very infrequently. The WSIP would not alter water levels in Lake Eleanor such that they would be substantially outside the range experienced under the existing condition.

Flow in Eleanor Creek below Eleanor Dam

Releases from Lake Eleanor with the WSIP and under the existing condition would be the same and would be at least equal to the fishery release schedule. Thus, the WSIP would have no effect on flow in Eleanor Creek.

Impact Conclusions

The WSIP would not alter releases to Eleanor Creek. Adverse impacts on flow in Eleanor Creek would be *less than significant*, and no mitigation measures would be required.

Impact 5.3.1-4: Effects on flow along the Tuolumne River below La Grange Dam.

Reservoir Operations

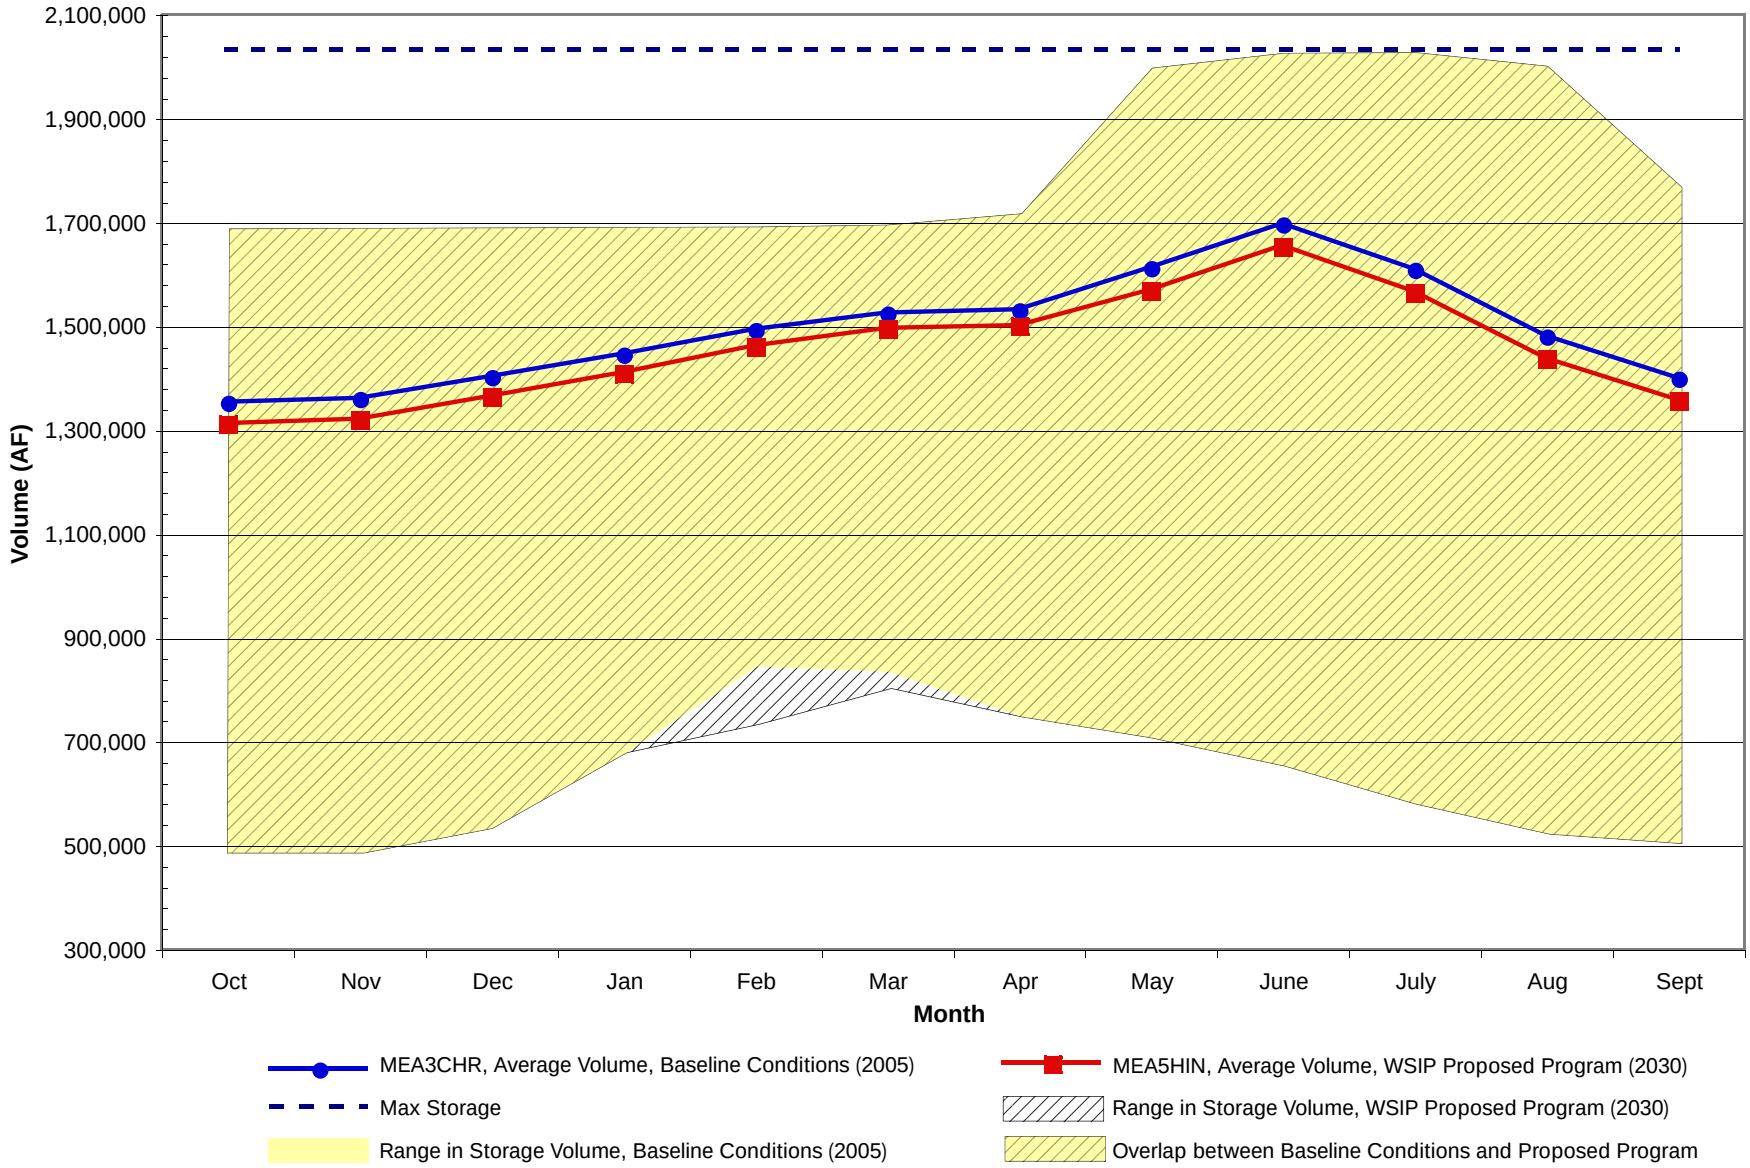
Don Pedro Reservoir, operated by TID, stores water from the upper Tuolumne River. Under typical conditions, the reservoir begins to fill with rainfall runoff from lower elevations in November and continues to fill through the winter and spring with a combination of rainfall runoff and snowmelt from higher elevations. The reservoir is drawn down from June through October to meet demand for irrigation supply in the TID and MID service areas.

Don Pedro Reservoir is a multipurpose facility that provides water supply and flood control benefits as well as recreational opportunities. To provide a prescribed level of downstream flood protection, storage space must be kept available in Don Pedro Reservoir to store floods that might occur. The space maintained in the reservoir for floodwater is referred to as the “flood control reservation.” It increases from zero on September 8 to 340,000 acre-feet on October 7. The reservation is maintained at 340,000 acre-feet until April 27, after which it declines to zero again by June 3.

The WSIP would not change TID’s operational goals for Don Pedro Reservoir or the flood control reservation requirements, but it would affect water levels in the reservoir and the magnitude and timing of releases to the Tuolumne River.

Water Storage and Water Levels in Don Pedro Reservoir

The WSIP would reduce average monthly storage in Don Pedro Reservoir year-round compared to the existing condition. **Figure 5.3.1-11** shows the average monthly storage and the range of monthly storage in the reservoir with the WSIP and under the existing condition. The



SOURCE: SFPUC, HH/LSM (see Appendix H)

Figure 5.3.1-11
Average Monthly Storage Volume,
Don Pedro Reservoir

decrease in stored volume is primarily attributable to increased water demand in the service areas of the SFPUC and its customers. As demand increases, so do diversions of water at Hetch Hetchy Reservoir for delivery to the Bay Area. As a result, less water flows down the Tuolumne River to Don Pedro Reservoir. Because of the decrease in stored volume in Don Pedro Reservoir with the WSIP, monthly average water levels would fall by 1 to 10 feet compared to the existing condition.

Figure 5.3.1-12 shows modeled chronological storage in Don Pedro Reservoir and releases to the Tuolumne River at La Grange Dam using hydrology from the period 1920 to 2002. The figure compares the WSIP to the existing condition. It shows that, under the existing condition, TID and MID fills Don Pedro Reservoir in the winter and draws from storage to meet agricultural water demand in the summer and early fall. Because the storage capacity of Don Pedro Reservoir is greater than the average volume of runoff produced in its watershed, TID and MID is unable to fill the reservoir completely every year. Currently, TID and MID is able to fill to its allowable October to April maximum storage capacity about 51 percent of the time and to its maximum physical capacity about 27 percent of the time. In the future with the WSIP, these values would be reduced to 48 percent and 21 percent.

The reductions in stored volume and lowering of water levels attributable to the WSIP would be greatest in critically dry years, particularly following a sequence of dry years. In average critically dry years, Don Pedro Reservoir would be drawn down 10 feet more in September than under the existing condition. The WSIP would lower water levels in Don Pedro Reservoir in some months during severe droughts by up to 27 feet compared to the existing condition.

The WSIP would not alter water levels in Don Pedro Reservoir such that they would be substantially outside the range experienced under the existing condition. Almost all of the time, storage in Don Pedro Reservoir fluctuates between its maximum capacity of 2,080,000 acre-feet, which corresponds with a water level of 834 feet above mean sea level, and 900,000 acre-feet, which corresponds with a water level of 714 feet. Thus, under the existing condition and almost all of the time, the water level fluctuates between 834 feet and 714 feet, a range of 120 feet. With the WSIP, the water level in Don Pedro Reservoir would fluctuate within the same range almost all of the time.

Occasionally, in extended droughts, storage in Don Pedro Reservoir would be drawn down severely. Under the existing condition, the water level in the reservoir would be drawn down to 643 feet, or 191 feet below the maximum, once in the 82-year hydrologic record. With the WSIP, the water level would be drawn down to essentially the same level once in the 82-year hydrologic record, but it would never be drawn down below that level. Thus, water levels with the WSIP would remain substantially within the same range as occurs under the existing condition.

SFPUC Water System Improvement Program ▪ 203287

Figure 5.3.1-12
Don Pedro Storage and La Grange Releases to the Tuolumne River

Flow in the Tuolumne River below La Grange Dam

Figure 5.3.1-12 shows the frequency and magnitude of modeled chronological releases from La Grange to the Tuolumne River under the existing condition and with the WSIP. Under the existing condition, releases to the Tuolumne River are at least equal to the fishery release schedule shown in Table 5.3.1-3. In most below-normal or drier years, almost all the winter and spring runoff from the watershed upstream of Don Pedro is captured in the reservoir. In years when the reservoir fills, usually wet or above-normal years, excess water is released to the Tuolumne River.

In the future with the WSIP, MID and TID would draw Don Pedro Reservoir down farther in many years than it would under the existing condition as shown in Figure 5.3.1-12. Consequently, MID and TID would have to capture a greater proportion of spring runoff to refill the reservoir with the WSIP. As a result, the volume of water released to the Tuolumne River would be reduced compared to the existing condition but would be at least equal to the required releases to support fisheries shown in Table 5.3.1-3.

Average monthly flows in the Tuolumne River immediately below La Grange Dam in different hydrologic year types for the existing condition and with the WSIP are shown in **Table 5.3.1-6**. The percentage change in average monthly flow attributable to the WSIP is also shown in the table. The WSIP would have little or no effect on average monthly flow in most summer, fall, and winter months in all hydrologic year types. The WSIP would have no effect on average monthly flow in any months of critically dry years or in most summer months of dry, below-normal, and above-normal years. Only the required fishery release would be made in these months under the existing condition and with the WSIP. With the WSIP, the number of months in which only the required fishery release would be made would increase slightly. Under the existing condition, the model indicates that the minimum release would be made 72.6 percent of the time (717 months in the 987-month hydrologic record); with the WSIP the minimum release would be made 74.4 percent of the time (734 months in the 987-month hydrologic record).

The WSIP would typically result in reductions of less than 10 percent in average monthly flow in the Tuolumne River below La Grange Dam in the November through June period when TID fills Don Pedro Reservoir, although reductions in average monthly flow could be as high as 25 percent. Reductions in flow would occur in some months of all year types, except for critically dry years. For example, in June of an average above-normal year, flow in the Tuolumne River below La Grange Dam would be 408 cfs under the existing condition; with the WSIP it would be 306 cfs, a reduction of 25 percent.

The absolute and percentage changes in flow in the Tuolumne River below La Grange Dam in individual months of wet, above-normal, below-normal, and dry years in the 82-year hydrologic simulation attributable to the WSIP vary widely. The chronological analysis shows that the maximum percentage reduction in average monthly flow attributable to the WSIP would be about 92 percent, occurring in one month in the 82-year hydrologic simulation. In that month, June 1993, the flow below La Grange Dam under the existing condition would be 3,409 cfs; with the WSIP it would be 250 cfs. Reductions in average monthly flow of 30 percent or more would occur in some months of 17 springs in the 82-year simulation, or about once in every four springs on average.

SOURCE: SFPUC, HH/LSM (see Appendix H).

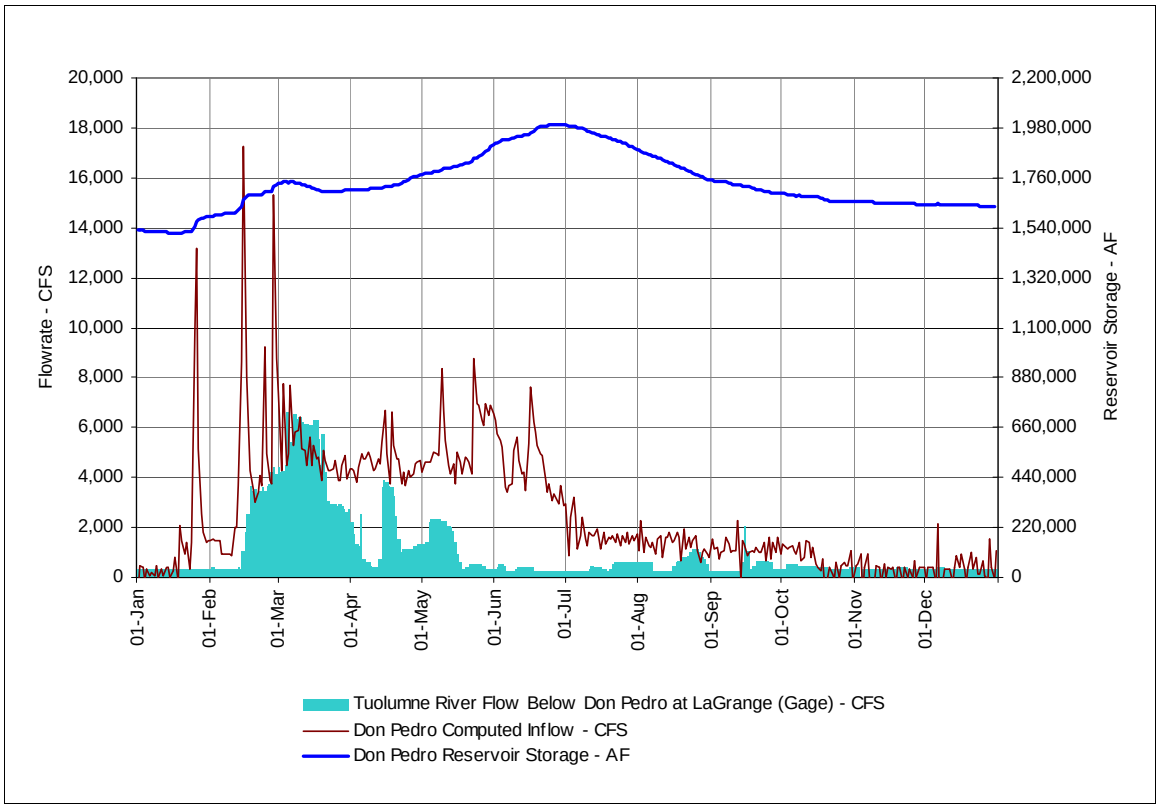
The results presented above are described in terms of average monthly flows because the HH/LSM is a monthly time-step model. TID's actual operational decisions may occur in smaller time steps, perhaps daily or weekly, depending on meteorological and operational circumstances. These within-month operational changes cannot be simulated with the HH/LSM, nor can the model be used to estimate the effects of the WSIP on peak flows in the river, because the peaks may only last for a few hours or days.

Insight into the effects of the WSIP on peak flows below La Grange Dam can be obtained by examining operational data. **Figure 5.3.1-13** shows actual data for 2000, an above-normal year; the greatest effects on peak flows would occur in wet and above-normal years. The figure shows storage in Don Pedro Reservoir falling slightly in the first half of January and then increasing to a maximum of about 2 million acre-feet at the end of June, as first rainfall runoff and then snowmelt enters the reservoir. Through January and the first half of February, TID added to storage in the reservoir and released only the minimum required to the Tuolumne River below La Grange Dam. In mid-February, faced with increasing quantities of rainfall runoff, the operators began to release water to the Tuolumne River in excess of the minimum required in order to maintain the required flood control storage reservation. Releases in excess of the minimum continued though March, April, and the first half of May. Beginning in April, the required flood control reservation decreased, enabling TID to add more water to storage. In mid-May, the operators reduced releases to the river, which remained at or close to the minimum for the remainder of the year. Measured flow in the Tuolumne River below La Grange Dam shows a number of step increases and decreases in flow from mid-February to mid-May lasting several days, as operators sought to balance reservoir inflow, gains in storage, and releases to the river in response to changing conditions.

If the WSIP had been in place in 1999, and water demand was at 2030 levels, storage during December in Don Pedro Reservoir (its seasonal low point) would have been about 1,600,000 acre-feet, similar to but less than under the existing condition. Needing to capture a slightly higher proportion of runoff with the WSIP than under the existing condition, operators would likely delay releases of water to the lower Tuolumne River in excess of minimum requirements by a few days. After the initial delay, the releases to the river with the WSIP would follow the same pattern as under the existing condition and would be of a similar magnitude.

The pattern and magnitude of releases from La Grange Dam to the Tuolumne River with the WSIP in any particular year would depend on meteorological and operational circumstances, as they do under the existing condition. Under the existing condition, there would be no releases from the dam to the river in excess of the minimum required release in 31 years of the 82-year hydrologic record. With the WSIP, there would be no releases above the minimum required in 33 years of the hydrologic record. In years when a release above the minimum required is made, the WSIP would delay the release of water and reduce the total volume of releases to the river in the winter and spring compared to the existing condition.

Releases from Don Pedro Reservoir and La Grange Dam follow a different pattern than releases from Hetchy Hetchy Reservoir. Hetch Hetchy Reservoir typically receives most of its water from



SFPUC Water System Improvement Program ▪ 203287

Figure 5.3.1-13
Don Pedro Reservoir Storage and Inflow,
Calendar Year 2000

snowmelt between early May and late July. Don Pedro Reservoir receives runoff over a longer period from both winter rainstorms and snowmelt. Furthermore, unlike Hetch Hetchy Reservoir, Don Pedro Reservoir is used to reduce downstream flooding. As a consequence, management of Don Pedro Reservoir is complex, and releases from the reservoir often occur in a series of pulses rather than in single episode as typically occurs at Hetch Hetchy Reservoir. In years when several pulse releases above the minimum required are made, the WSIP might eliminate one or more of the pulse releases and would delay others by several days or weeks.

After an unusual series of dry years, when Don Pedro Reservoir is drawn down substantially farther with the WSIP than under the existing condition, winter and spring releases above the minimum required would occasionally be eliminated or almost eliminated. This circumstance is illustrated by the sequence of hydrologic conditions that occurred between 1986 and 1993. Although the WSIP would commonly reduce winter and spring flow in the river below La Grange Dam, it would not affect very infrequent large peak flows produced primarily by rainstorms.

Impact Conclusions

The WSIP would not alter stream flow in the Tuolumne River below La Grange Dam such that it would be substantially outside the range experienced under the existing condition, nor would the flow alterations result in adverse hydrologic effects or be sufficient to change the character of the river. Large, infrequent peak flows under the existing condition and with the WSIP would be similar in magnitude. Minimum flows are the subject of an agreement with the FERC and would the same with the WSIP as under the existing condition.

Overall, the effects of the WSIP on flow along the Tuolumne River below La Grange Dam would be *less than significant*, and no mitigation measures would be required.

Impact 5.3.1-5: Effects on flow along the San Joaquin River and the Sacramento–San Joaquin Delta.

The Tuolumne River joins the San Joaquin River about 50 miles downstream of La Grange Dam. The reductions in flow in the Tuolumne River below La Grange Dam attributable to the WSIP are shown in Table 5.3.1-6. The WSIP would reduce flows in the Tuolumne River between La Grange Dam and its confluence with the San Joaquin River, and in the San Joaquin River from the confluence to the Delta. Most of the reductions in flow would occur from January through June in wet or above-normal years, when flow in the San Joaquin River is at its seasonal maximum. The greatest reductions would occur in years following extended droughts when storage in Don Pedro Reservoir is being replenished. For example, under hydrologic conditions that prevailed in February 1936, average monthly flow in the San Joaquin River between the Tuolumne and Stanislaus River confluences would be reduced from about 10,000 cfs to 7,500 cfs under the WSIP compared to existing conditions. Similarly, under June 1993 conditions, average monthly flows would be reduced from about 7,000 cfs to 3,500 cfs. Flow reductions of these magnitudes would be rare events occurring four or five times in the 82-year period of hydrologic record.

The SWRCB has established flow objectives for the San Joaquin River at Vernalis, just upstream of the Sacramento–San Joaquin Delta. Almost all of the time, the reductions in San Joaquin River flow attributable to the WSIP would not be sufficient to cause flow in the river at Vernalis to fall below the objective. Very infrequently, following protracted droughts, reductions in San Joaquin River flow attributable to the WSIP would be sufficient to cause flow in the river at Vernalis to fall below the objective. Under these circumstances, the USBR, the agency responsible for compliance with objectives for the San Joaquin River, would be expected to increase releases from New Melones Reservoir on the Stanislaus River to meet the flow objectives at Vernalis. Thus, the WSIP would not alter flow in the San Joaquin River below its confluence with the Tuolumne River such that it would be substantially outside the range experienced under existing conditions nor result in a violation of flow objectives.

The reductions in flow in the Tuolumne River below La Grange Dam attributable to the WSIP would also reduce inflow to the Sacramento–San Joaquin Delta. The SWRCB has established

objectives for Delta outflow as measured at Chipps Island, just upstream of Suisun Bay. Almost all of the time, the reductions in Delta inflow attributable to the WSIP would not be sufficient to cause Delta outflow to fall below the objective. Very infrequently, following protracted droughts, reductions in Delta inflow attributable to the WSIP would be sufficient to cause Delta outflow to fall below the objective. Under these circumstances, the USBR and DWR, the respective operators of the Central Valley Project and State Water Project, would be expected to decrease their diversions so that the Delta outflow objectives were met. Thus, the WSIP would not alter flow in the Sacramento–San Joaquin Delta such that it would be substantially outside the range experienced under the existing condition.

Overall, the effects of the WSIP on flow along San Joaquin River and in the Delta would be *less than significant*, and no mitigation measures would be required. Additional information on the effects of the WSIP on flows in the San Joaquin River and the Delta is provided in Section 5.3.4.

5.3.2 Geomorphology

Channel morphology, or river form, reflects the interactions among watershed geology, flow, the supply of sediment and large woody debris, tectonic uplift and subsidence, and glacial advances and retreats. River channels are in a state of dynamic equilibrium with their watersheds. Although they may change each year, particularly in response to high flows, their characteristics remain stable in the medium term, provided conditions in the watershed also remain stable. When conditions in a watershed change, the dynamic equilibrium is disturbed, and river form will adjust to the new watershed condition (Knighton, 1984).

Over the last century, flow in the Tuolumne River between Hetch Hetchy Reservoir and Don Pedro Reservoir and below La Grange Dam has been progressively reduced by dam operations and the diversion of water for hydropower generation, flood control, and municipal and agricultural water supply. The WSIP would cause further changes in river flow over the next 25 years, as described in Section 5.3.1. Thus, WSIP-induced changes in river flow have the potential to further affect river channel characteristics.

5.3.2.1 Setting

The Tuolumne River drains a 1,960-square-mile watershed on the western slope of the Sierra Nevada range and is the largest of three major tributaries to the San Joaquin River. The river originates in Yosemite National Park and flows southwest to its confluence with the San Joaquin River, approximately 10 miles west of the city of Modesto. Deep canyons, granite river channels, and forested, mountainous terrain characterize the watershed between its crest and La Grange Dam. Near the town of La Grange, the river exits the Sierra Nevada foothills and flows through a gently sloping alluvial valley that is incised into Pleistocene alluvial fans.

Upper Tuolumne River and Tributaries

Upstream of Don Pedro Reservoir, the Tuolumne River and its tributaries flow through steep narrow valleys that confine the river channel. In most of this reach, the river channel is steep and alternates between bedrock chutes,[1] boulder cascades, and pools. Except in the Poopenaut Valley (a 2.5-mile reach below O'Shaughnessy Dam) and downstream of the Clavey River confluence, alluvial deposits are limited to small or medium-sized patches associated with flow obstructions (such as boulders and bedrock outcrops). For the first 2.5 miles below O'Shaughnessy Dam, the Tuolumne River flows through a U-shaped glaciated valley. The river channel is V-shaped and sinuous in the approximately 10 miles of river from the Poopenaut Valley to Early Intake. While the average channel gradient in this reach of the river is steep (averaging 2 percent), subreach-scale variation in channel gradient and valley confinement provides very diverse channel morphology. Channel morphology in this reach ranges from the low-gradient, sand-bedded channel and broad wetland meadow of the Poopenaut Valley to the steep, bedrock-confined channel found in most of the rest of the Tuolumne River (McBain & Trush and RMC, 2006).

[1] A chute in this context is an inclined trough or channel feature such as a waterfall or rapid.

From Early Intake, the river flows about 10 miles to its confluence with the South Fork of the Tuolumne River. The river is confined in a deeply incised, V-shaped canyon with steep, competent side slopes. Channel gradient in this reach also averages about 2 percent, but is as steep as 4 percent in one section. For most of its length, the channel consists of a series of pools separated by steep cascades over boulders. Alluvial bars and side-channels are present throughout the reach where the valley widens or where bedrock constraints reduce channel gradient.

From the South Fork confluence to the upper end of Don Pedro Reservoir, the average channel gradient decreases to less than 1 percent. In the upper section of this reach, from the confluence with the South Fork to the confluence with the Clavey River, the river channel consists of boulder cascades separated by medium-length pools. Downstream of the Clavey River confluence, the channel gradient decreases, and the channel becomes semi-alluvial. Large boulder bars are common.

Cherry Creek is a tributary to the Tuolumne River. From Cherry Dam, Cherry Creek flows about 12 miles to its confluence with the Tuolumne River (1.3 miles downstream of Early Intake). For most of this length, Cherry Creek is confined within a narrow bedrock canyon, and channel gradient is steep (5 percent). The bed consists primarily of boulders and bedrock, although a large volume of sand is stored in pools. Immediately downstream of the dam, however, the channel alternates between low-gradient, gravel-bedded reaches separated by steep, bedrock chutes. In the gravel-bedded reaches of the upper five-mile reach between the dam and the confluence with Eleanor Creek, riparian and upland vegetation has encroached onto formerly active alluvial bars since completion of Cherry Dam.

Eleanor Creek flows into Cherry Creek seven miles upstream of the Tuolumne River and extends 3.5 miles from Eleanor Dam to Cherry Creek. For most of its length, Eleanor Creek flows through a steep bedrock canyon, and the channel is a series of pools and falls. The average channel gradient is 6 percent.

A common perception is that bedrock channel morphology is static compared to alluvial channels and therefore relatively insensitive to flow and sediment supply changes (e.g., Montgomery and Buffington, 1997). Bedrock channels, however, are often highly dynamic depositional environments; though principally erosional, they also exhibit abundant depositional features. Large, geomorphically derived hydraulic controls, such as width constrictions or expansions and resistant bedrock outcrops, remain stable over decades or centuries and define an overall limit for coarse sediment deposition in each segment of the bedrock channel. These geomorphic controls induce coarse depositional features that in turn perform as smaller hydraulic controls to induce finer and more transitory secondary depositional features. The occurrence of smaller hydraulic controls within larger hydraulic controls gives rise to a complex, nested depositional channel morphology that provides diverse aquatic and riparian habitats (McBain and Trush, 2004).

Short channel segments where channel gradient decreases and/or valley width increases may support unique and/or more diverse aquatic and riparian communities. These atypical channel segments exhibit prominent depositional features, such as alluvial bars, side channels, and limited floodplains. While these alluvial subreaches and patches constitute a small portion of the channel

in this reach, they provide important establishment sites for riparian vegetation, habitat for aquatic flora and fauna and native amphibians, and low-velocity rearing habitat for juvenile fish.

Sediment is supplied to bedrock rivers primarily through "mass wasting." Hill-slope mass wasting, such as rock falls and bedrock shearing from canyon walls, episodically delivers coarse sediment of sufficient volume and/or caliber to create large depositional features in the channel or to function as large-scale hydraulic controls capable of generating other prominent depositional features. Bedrock rivers have a huge potential transport capacity for coarse sediment, but a small storage capacity for coarse and fine sediment. Hydraulic complexity and channel form, expressed as nested hydraulic controls in a variable flow regime, exert the greatest control on storage capacity. The annual coarse bedload[2] transported may fluctuate dramatically without significantly affecting the volume of coarse sediment stored in a channel segment. Although storage capacity is low, the ecological implications for maintaining these limited depositional features can be great.

In bedrock rivers, diverse erosional and depositional features are created and maintained by a broad range of floods. For example, sand patches are scoured and deposited during small floods, while boulder ribs are mobilized only during very large, infrequent floods. Flow thresholds that mobilize depositional features in bedrock rivers are not well understood. Recent, though limited, observations of the Clavey River (a tributary to the Tuolumne River) suggest that:

- Common small floods that occur every one to three years scour and deposit sand at pools and bars
- Moderate-sized floods that occur every 12 to 17 years move gravel and cobbles, reshape side channels, and may move large woody debris
- Very large floods that occur every 70 to 100 years erode large bars, remove and create side channels, and move large boulders over short distances

Tuolumne River from La Grange Dam to the San Joaquin River

Near the town of La Grange, the Tuolumne River exits the Sierra Nevada foothills and flows through a gently sloping alluvial valley incised into Pleistocene alluvial fans. The valley walls confine the river corridor to as narrow as 500 feet near Waterford, about 20 miles downstream of La Grange, whereas the river reaches downstream of Modesto are virtually unconfined. In some locations, bedrock outcrops control the gradient of the river; in others, the bedrock is up to 50 feet below the riverbed.

Within the alluvial valley, the river can be divided into two geomorphic units defined by channel slope and bed composition: the gravel-bedded reach, which extends about 28 miles from La Grange Dam to below Geer Road, and the sand-bedded reach, which extends about 24 miles from below Geer Road to the confluence with the San Joaquin River. The gravel-bedded reach has moderate slopes (0.03–0.15 percent), and extensive alteration of the channel and floodplain

[2] Refers to the amount of cobbles, gravel, and sand transported along the stream bottom (as opposed to suspended in the stream flow).

has occurred as a result of past gold dredging operations and past and current aggregate mining. Channel gradient decreases to less than 0.03 percent in the sand-bedded reach, and the channel is characterized by a meandering, alternate bar morphology. Under current conditions, coarse sediment sources are limited to tributaries downstream of La Grange Dam and to bed and bank erosion, so little coarse sediment enters the lower river. Most of the sediment that is currently contributed to the channel downstream of the dam consists of sand and finer-sized particles. While dams have eliminated upstream sediment supply, gold dredging and aggregate mining have removed sediment stored in the river channel and floodplain. Since sediment supply to the lower river has been cut off by upstream dams, the river cannot recover from past in-channel dredging and mining.

Operation of Don Pedro Reservoir has reduced the magnitude of peak flow in the lower river, and the reduction in peak flows has altered channel characteristics below La Grange Dam. Flood releases from the reservoir are dictated by three factors:

- Maximum releases through the dam outlet works (14,000 cfs)
- U.S. Army Corps of Engineers flood control rules, which limit flows to 9,000 cfs, as measured at the Modesto gauge (which includes inflows from Dry Creek)
- Maximum release capacity through the powerhouse turbines (5,500 cfs)

A number of agencies and nonprofit groups, including the SFPUC, TID, MID, U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NMFS), California Department of Fish and Game (CDFG), Friends of the Tuolumne, and the Tuolumne River Preservation Trust, are cooperating in efforts to restore the lower Tuolumne River corridor. In 2000, the Tuolumne River Technical Advisory Committee completed the *Habitat Restoration Plan for the Lower Tuolumne River Corridor* (McBain & Trush, 2000). The goal of the plan is to improve the river's value as fish and wildlife habitat. The plan recommends several measures to improve ecological function in the lower river, including increased frequency and magnitude of high flows, channel reconstruction, and coarse and fine sediment management. Recommended increases in flood flows, which would be achieved through revisions to operating criteria during flood control release periods, would increase the magnitude of bankfull[3] flows to more effectively move sediment. Of the 14 channel restoration projects identified in the plan, two have been constructed, two will be constructed in 2007, and three have complete designs and are in various stages of funding and implementation planning. Peak flows below La Grange Dam are usually in the range of 5,000 to 5,500 cfs as a result of reservoir releases for power generation purposes. Consequently, all of these restoration projects are designed to function based on a bankfull flow and two-year flood of 5,000 cfs (McBain *et al*., 2004).

[3] A bankfull channel conveys commonly occurring flows, with larger flows spilling over the banks and onto the floodplain.

5.3.2.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to geomorphology, but generally considers that implementation of the proposed program would have a significant impact if it were to:

- Substantially change the topography such that ecological, hydrologic or aesthetic functions are adversely affected, or substantially change any unique geologic or physical features of the site or area

- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of the stream or river, in a manner that would result in substantial erosion or siltation or adversely affect the ecological, hydrologic or aesthetic functions of the site or area

Although the "substantial change in topography" criterion is typically applied to upland areas, it is considered applicable to stream channel/bank topography in this instance because of the sensitivity of the resources that depend on the topography of those features (i.e., riparian vegetation and fisheries).

Approach to Analysis

This impact section presents a discussion of the potential changes in sediment transport and geomorphology that could result from WSIP-related changes in stream flow, reservoir storage, and reservoir water levels, as described in Section 5.3.1. A qualitative assessment of potential effects was conducted based on generalized channel bed/bank characteristics and a consideration of the program-induced changes in stream flow. No modeling or field measurements have been performed to estimate program-generated changes in sediment transport in the Tuolumne River system.

As indicated in Section 5.3.1, the WSIP would have no effect on flow in Cherry Creek or Eleanor Creek. Consequently, the impact analysis focuses on the Tuolumne River between Hetch Hetchy Reservoir and the confluence with the San Joaquin River, a reach of the river that would be affected by WSIP-induced changes in stream flow.

Impact Summary

Table 5.3.2-1 presents a summary of the impacts on sediment transport and geomorphology in the Tuolumne River system and downstream water bodies that could result from implementation of the proposed water supply and system operations.

TABLE 5.3.2-1
SUMMARY OF IMPACTS –
GEOMORPHOLOGY OF THE TUOLUMNE RIVER SYSTEM AND DOWNSTREAM WATERBODIES

Impact	Significance Determination
Impact 5.3.2-1: Effects on sediment transport and channel characteristics between O'Shaughnessy Dam and Don Pedro Reservoir	LS
Impact 5.3.2-2: Effects on sediment transport and channel characteristics below La Grange Dam	LS

LS = Less than Significant impact, no mitigation required

Impact Discussion

Impact 5.3.2-1: Effects on sediment transport and channel characteristics between O'Shaughnessy Dam and Don Pedro Reservoir.

Sediment transport and channel characteristics are primarily influenced by peak flows rather than by smaller common flows. As noted above, studies of the Clavey River indicate that peak flows that occur every one to three years produce enough energy to move sand; peak flows that occur every 12 to 17 years produce enough energy move gravel and cobbles; and peak flows that occur every 70 to 100 years produce enough energy to move boulders. Although the relationship between peak flows and the transport of sand, gravel, and boulders for the Clavey River cannot be directly applied to the main stem of the Tuolumne River, it provides an indication of the frequency of peak flows that mobilize depositional features in steep, mountain streams.

As discussed in Section 5.3.1 and illustrated in Figure 5.3.1-9, the WSIP would have little effect on the very large and infrequent floods in the Tuolumne River between O'Shaughnessy Dam and Don Pedro Reservoir that are capable of moving boulders and altering the characteristics of the bedrock channels. When the volume of runoff from the watershed above Hetch Hetchy Reservoir is great, the reservoir fills rapidly, after which all flow in excess of the capacity of the reservoir and Mountain Tunnel is released to the river. Under these conditions, the WSIP would extend the reservoir refill period and delay releases from the reservoir slightly (for a few days), after which releases to the river would follow the same pattern as they do under the existing condition. Because the WSIP would not affect the frequency or magnitude of large and infrequent floods, it would have a less-than-significant effect on the bedrock channel characteristics of the Tuolumne River below O'Shaughnessy Dam, and no mitigation measures would be required.

Flow in the Tuolumne River between O'Shaughnessy Dam and Early Intake consists predominantly of controlled releases from Hetch Hetchy Reservoir, except during large storms or snowmelt runoff. Under certain conditions (e.g., in normal hydrologic years that follow extended droughts), the WSIP could reduce the magnitude and duration of bankfull peak flows that are released from the reservoir every one to three years. As shown Figure 5.3.1-9, reductions in peak flows of this type occur infrequently in the 82-year hydrologic record. Thus, the WSIP could affect the rate and amount of sediment deposition and erosion in side channels and in the vicinity

of the few streamside meadows that exist in this reach of the river. However, because the changes in peak flow would occur infrequently, they would not be expected to result in a substantial change in erosion or siltation rates. The impact would be *less than significant*, and mitigation measures would not be required.

Impact 5.3.2-2: Effects on sediment transport and channel characteristics below La Grange Dam.

As noted above, the bankfull peak flows that occur every one to three years are the primary channel-forming events in the reach of the Tuolumne River below La Grange Dam, although larger floods are also important. The WSIP would have little effect on very large and infrequent floods within the Tuolumne River below La Grange Dam, such as the flood that occurred in 1997, but could affect the magnitude of the bankfull peak flows.

The WSIP would increase the drawdown of Don Pedro Reservoir by a small amount each year and by a considerable amount in an extended drought. To refill the reservoir in the winter and spring, TID and MID would capture a larger proportion of runoff than it does under the existing condition. In some years, when runoff is great compared to the storage deficit, the WSIP might extend the reservoir refill period and delay releases from Don Pedro Reservoir by several days, after which releases from the reservoir would follow the same pattern as they do under the existing condition. Under these conditions, the WSIP would have little or no effect on channel geomorphology. Occasionally, refilling the reservoir would require most or all runoff in excess of the minimum required fish release, and flows below La Grange Dam would be substantially reduced compared to the existing condition. In these years, sediment transport in the river below La Grange Dam would be reduced. However, because WSIP-induced changes in peak flow would occur infrequently, they would not be expected to result in a substantial change in erosion rates, siltation rates, or channel form. The impact would be *less than significant*, and mitigation measures would not be required.

5.3.3 Surface Water Quality

The following setting section describes surface water quality in streams and reservoirs in the Tuolumne watershed and downstream water bodies that could be affected by the WSIP. The impact section (Section 5.3.3.2) provides a description of the changes in water quality in streams and reservoirs that would result from WSIP-induced changes in stream flow and reservoir water levels.

5.3.3.1 Setting

The Tuolumne River flows from the crest of the Sierra Nevada westward to its confluence with the San Joaquin River. The San Joaquin River flows north to the Sacramento–San Joaquin Delta. Water from the Delta discharges to the San Francisco Bay Estuary and the Pacific Ocean. The Tuolumne River system and downstream water bodies are shown in Figure 5.1-1.

The WSIP would affect flow in the Tuolumne River, the San Joaquin River, and the Sacramento–San Joaquin Delta as well as water levels in Hetch Hetchy Reservoir and Don Pedro Reservoir, as described in Section 5.3.1. WSIP-induced changes in flow and water levels could affect water quality in these streams and reservoirs. The WSIP would have minor effects on flow in Eleanor and Cherry Creeks and on water levels in Lake Eleanor and Lake Lloyd, but the changes would be too small to affect water quality.

The water supply and system operations components of the WSIP would not involve the discharge of pollutants into water bodies and therefore would have a limited potential to affect water quality. WSIP-related changes in water quality, such as changes in water temperature or dissolved oxygen, would stem from changes in stream flow and changes in water levels in reservoirs. Accordingly, the water quality data presented in this section are limited to those water quality characteristics that could be altered by elements of the proposed program or that are needed to provide a general understanding of potentially affected water bodies.

Tuolumne River

Water quality in the upper Tuolumne River basin is excellent. The Tuolumne River drainage above Hetch Hetchy Reservoir lies entirely within the less developed parts of Yosemite National Park. The combination of a high-altitude granitic drainage basin and minimal human influences results in river water that is cold, clear, and free of contaminants. Water quality in Hetch Hetchy Reservoir is also excellent. Plant nutrients such as nitrogen and phosphorus are typically near or below detection limits, and dissolved oxygen concentrations are typically at or near saturation. Total dissolved solids concentrations are less than 10 milligrams per liter (mg/L), and average total organic carbon concentrations are less than 2 mg/L. The SFPUC samples water quality at various depths in Hetch Hetchy Reservoir. As shown in **Table 5.3.3-1**, monthly water temperatures at a depth of 140 feet below the water surface for the period from 1997 to the present ranged between 6.5 and 13.8 degrees Celsius (°C). This depth, which is approximately the middle of the water column, is representative of water released to the Tuolumne River.

TABLE 5.3.3-1
SUMMARY OF TEMPERATURE DATA (°C), HETCH HETCHY RESERVOIR

Year	Flow Index[a]	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec

[a] Flow Index is the year's total runoff as a percentage of the long-term average.

SOURCES: SFPUC (raw data); Merritt-Smith Consultants (data reduction).

Water quality in the reach of the Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs is very good, but its dissolved mineral and plant nutrient content increases somewhat in a downstream direction. MID samples water from the outlet of Modesto Reservoir on the Modesto Canal. The samples are reasonably representative of water quality in the Tuolumne River at La Grange Dam. Total dissolved solids have been measured twice daily since 1997. These data show total dissolved solids concentrations that range from 15 to 26 mg/L, with an average of about 20 mg/L.

Below Don Pedro Reservoir, Tuolumne River water quality deteriorates somewhat as a result of agricultural irrigation return flow, urban and agricultural runoff, and recreation in and around the river and in Don Pedro Reservoir itself. In the warmer months, water temperature increases in a downstream direction as the river leaves the foothills of the Sierra Nevada and flows on to the floor of the San Joaquin Valley. Total dissolved solids content and turbidity also increase in a downstream direction.

Water temperature at several stations on the Tuolumne River downstream of La Grange Dam has been recorded for many years, but most intensively and reliably in the last decade in the course of a 2005 TID/MID study. La Grange Dam is located at river mile (RM) 52.2; that is, it is 52.2 miles upstream of the Tuolumne River's confluence with the San Joaquin River. Daily average water temperature at RM 51.8, about one-half mile below La Grange Dam, was usually in the range of 9 to 14 °C between 1996 and 2004. Daily average temperature at RM 36.7, about 15 miles below La Grange Dam, was usually in the range of 9 to 26 °C, and at RM 3.4, about 50 miles below La Grange Dam, was usually in the range of 9 to 29 °C. Daily average wintertime water temperature is similar for the entire river reach from La Grange Dam to the confluence with the San Joaquin River. The maximum temperatures experienced in the summer and fall from 1996 to 2004 at several locations are shown in **Table 5.3.3-2**. Seasonal variation at RM 43.4, about nine miles below La Grange Dam is shown in **Figure 5.3.3-1**.

TABLE 5.3.3-2
MAXIMUM SUMMER–FALL WATER TEMPERATURES IN THE TUOLUMNE RIVER FROM LA GRANGE DAM TO MODESTO[a]
1996–2004

Year	Water Year Type	Maximum Water Temperature (Summer–Fall) (°C rounded to nearest 0.5)				
		RM 49	RM 43.4	RM 36.7	RM 23.6	RM 3.4
1996	AN-W	18.5	**21**	**25**	NA	**29**
1997	AN-W	16	**20**	**23**	**26**	**28**
1998	W	14	16	17	**21**	**23**
1999	BN-AN	16	18	**23**	**27**	**29**
2000	BN-AN	NA	19	**23**	**27**	**28**
2001	D	**22**	**28**	**30**	**31**	NA
2002	D	**20**	**26**	**30**	**30**	**31**
2003	BN	16	19	**23**	**26**	**30**
2004	D	18	**24**	**27**	**30**	NA

[a] La Grange Dam is located approximately at RM 49 and Modesto at RM 3.4.

W = wet; AN = above normal; BN = below normal; D = dry; C = critically dry; RM = river mile
Temperatures ≥20 °C are shown in **bold** type.

The TID/MID study describes some general trends in water temperature:

- In all year types from 1996 to 2004, releases from Don Pedro Reservoir varied seasonally from a low of about 8 °C to a high of about 16 °C, with low temperatures occurring during the spring snowmelt and the highest temperatures occurring in late summer.

- In the reaches below Don Pedro Reservoir and La Grange Dam (RM 51.8 to RM 36.7), there is a clear relationship between hydrologic year type (and thus flow) and river temperatures during the summer and fall. This probably reflects the influence of surface-area-to-volume relationships. The effect becomes increasingly pronounced from upstream to downstream due to high summer temperatures in the San Joaquin Valley (Table 5.3.3-2). Even in wet years, peak summer temperatures in the reach downstream of RM 23.6 are above 20 °C. In all but the summer of 1998 following the extremely wet 1997/1998 floods, peak water temperatures exceed 20 °C up to RM 36.7.

- In downstream reaches of the river (RM 23.6 and below), the period of average daily temperatures in excess of 21 to 23 °C is frequently two to four months long.

The water temperature data from TID/MID(2005) are generally consistent with those reported in a 1996 FERC study. The FERC report notes that water temperature in the river is probably affected by the lack of riparian shade, and that leakage of water from diversion reservoirs and upwelling of groundwater probably provide some pockets of cool water in the summer.

Some water quality characteristics in the Tuolumne River are affected by reservoir operations and by changes in river flow attributable to water supply and hydropower generation activities. Primary among them is water temperature, which in turn may affect dissolved oxygen content. Water temperature in flowing streams depends on the water source, air temperature, flow, surface area, and exposure to solar radiation. Reductions in stream flow when air temperature is high usually

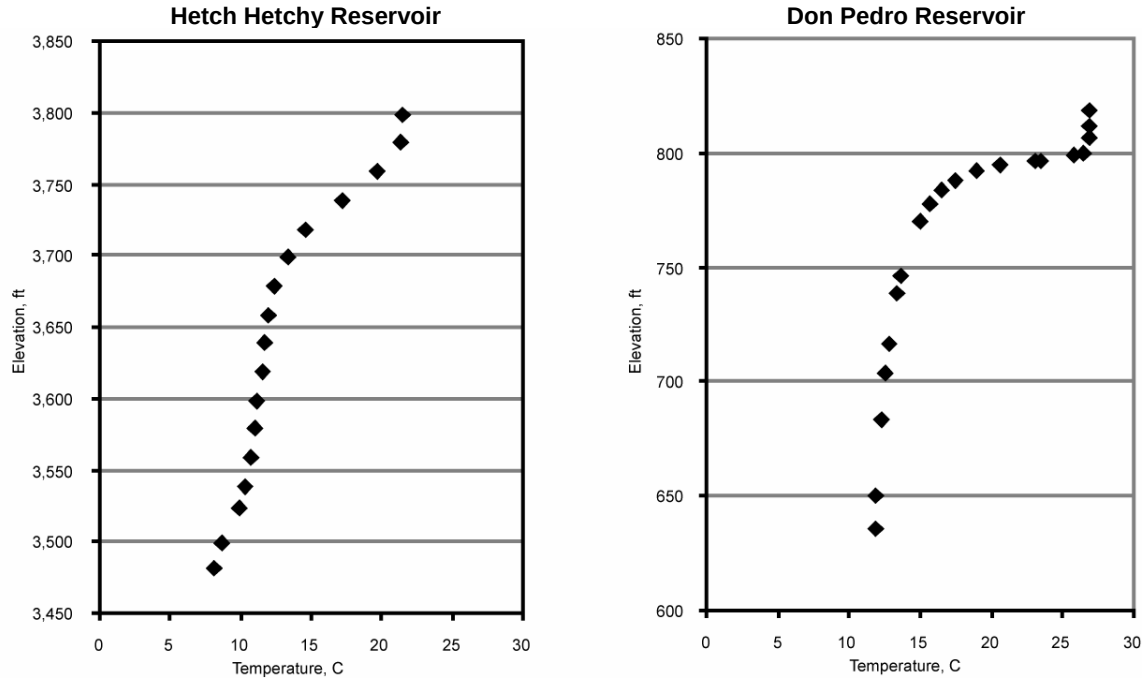
result in increases in water temperature. Storage of water in reservoirs may increase or decrease water temperatures. Hetch Hetchy and Don Pedro Reservoirs fill with cool water in the winter and spring. During the summer, water near the surface is heated by solar radiation, but because the reservoirs are deep they retain a large volume of cool water nearer the bottom. The boundary between the warmer surface waters and cooler waters below is referred to as the thermocline. The portions of the reservoir above and below the thermocline are referred to respectively as the epilimnion and the hypolimnion. The thermocline is quite distinct in most deep reservoirs in the Sierra Nevada and is typically at a depth of 25 to 50 feet below the water surface. **Figure 5.3.3-2** shows typical August temperature profiles for Hetch Hetchy and Don Pedro Reservoirs in August. Typical summertime water temperatures in the epilimnion and hypolimnion at Hetch Hetchy Reservoir are 20 °C and 10 °C, respectively. Corresponding values for Don Pedro Reservoir are 27 °C and 12 °C.



SFPUC Water System Improvement Program ▪ 203287

Figure 5.3.3-2
Typical Summertime Water Temperature Gradient in Hetch Hetchy and Don Pedro Reservoirs

Water is typically released to streams from outlets near the bottom of reservoirs. If water is released from a reservoir in the summer from below the thermocline, it is typically cooler than stream water would be if the reservoir did not exist. When reservoirs are drawn down in the late summer and fall, the thermocline moves downward, closer to the reservoir outlet. Releases from reservoirs at such times may be a mixture of cool bottom water and warmer water from nearer the surface, with a consequent increase in water temperature in the stream below the reservoir.

San Joaquin River
