		Age 16<70 Years k (Phase 1 operation)	230	9.75				1.6	1	0.0036

NOTES:

a Daily breathing rates are from OEEHA (2015) based on BAAQMD guidance (2016) as follows: for child residents, 95th percentile 24-hour breathing rates (OEHHA Table 5.6) for 3rd trimester and age 0<2 years and 80th percentile 24-hour breathing rates (OEHHA Table 5.7) for age 2<9 years, age 2<16 years, and age 16<30 years; for onsite child daycare, 95th percentile 8-hour moderate intensity breathing rates (OEHHA Table 5.8) for age 2<9 years; for worker, 95th percentile 8-hour moderate intensity breathing rates (OEHHA Table 5.8) for age16<70 years.

b Cancer risk for residential receptors are calculated based on 30 year exposure, the exposure duration for "Construction + Operation" scenario represents 1 year of Phase 1 construction, 10 years of Phase 1 operation, 1 year of Phase 2 construction with concurrent Phase 1 operation, and another 18 years of full operation after buildout. The EDs are separated into construction and operational exposures to more clearly identify the values used for each receptor group and exposure period. The exposure duration for "Full Operation" scenario represent 30 years of exposure to post-buildout full operational emissions. Cancer risk for offsite worker receptors are based on 25 year exposure. Exisitng businesses are assumed to remain until start of Phase 2 construction, correspondingly, cancer risk calculations for onsite workers are based on 11 years exposure that include 1 year phase 1 construction plus 10 years phase 1 operation, and that for onsite daycare (child 2.5 to 6 years) is based on exposure to 1 year Phase 1 construction plus 4 years of Phase 1 operation.

c There is no offsite schools within the study area (1000 ft from project boundary), so fraction of time at home used values from OEHHA (2015) Table 8.4.

d Exposure frequency represents default residential exposure frequency from BAAQMD guidance (2016). Onsite daycare are assumed to have the same schedule as workers.

e Averaging time represents 70 years for lifetime cancer risk, per OEHHA (2015).

f The Model Adjustment Factor is applied to adjust the annual average concentration from AERMOD associated with construction/operational emissions, to actual the actual construction/operation emission schedule and receptor exposure for daycare and worker receptors. The MAF conservatively assumes that all construction/operational emissions occur while the children or worker are at school/work, so the overlap in emissions and exposure is 100%. The MAF is based on the Worker Adjustment Factor (WAF) described by OEHHA (2015) in Section 5.4.1.2 and Table 5.10. WAF for construction phase assumes 8 hours per day and 5 days per week emissions (WAF equation = [24 hours / 8 hours] * [7 days / 5 days] = 4.2). WAF for operational emissions conservatively uses the Costco gas station's schedule of 15 hours per day and 7 days per week (WAF equation = [24 hours / 15 hours] * [7 days / 7 days] = 1.6).

g Age sensitivity factors from OEHHA (2015) Table 8.3

h IF_{inh} is calculated as follows: DBR * FAH * EF * ED * MAF * ASF * DF * CF / AT, where CF = 0.001 m^3/L. "Intake Factor (IFinh) - NO ED" takes out the ED from the equation so that a risk scaling factor is derived for a per-year scenario.

Onsite Daycare - Student Caner Risk Calculations

Total Cancer Risk (chances per million)

Phase 1 Operation	Phase 1 CSTN	Total
0.32	0.17	0.49

Notes:

1. The onsite daycare will be demolished during Phase 2 construction, and the daycare serves children ages two through pre-K (age 5). Therefore, for cancer risk calculation, onsite daycare receptors were assumed to be exposed to all Phase 1 construction emissions and a maximum of four years of Phase 1 operations.

2. Cancer risk calculation is based on 8 hours per day, and 250 days per year of exposure.

Operational Cancer Risk Per Year

AgeBin	X	Y	Cancer Risk (per million per year) Phase 1 Operation
2<9	595305.29	4173022.5	0.0807594

Operational GLC

Year	Pollutant	Phase	GLC (ug/m^3)	X	Y

ClubSportPleasant User - Cancer Risk Calculations

Total 30-year Exposure Scenarios' Cancer Risk Summary

CSTN+Op			
Operation	**CSTN**	**Total**	**Full Operation**
1.53	0.36	1.89	2.43

Notes:

1. The CSP facility's Kids World program allows a child of 6 weeks to 3 months old to stay at the facility for a maximum of one and half hours per day, and a child 3 months or older to stay for a maximum of four hours per day, through age 17. For cancer risk calculations, this HRA conservatively assumed an individual would be present four hours per day, seven days per week, 350 days per year from birth to 30 years old (representing a highly conservative and unlikely scenario of 30-year total

2. Scenario "CSTN+Op" evaluates cancer risk from all construction and operational activities from 2020 to 2050. Scenario "Full Operation" evaluates cancer risk from

EXECUTIVE SUMMARY

This technical memorandum (Memo) presents the updated criteria pollutant emissions analysis for Section 4.B – Air Quality of the 2015 Draft Supplemental Environmental Impact Report (SEIR) for the Johnson Drive Economic Development Zone project (Project) located in the City of Pleasanton, in support of environmental clearance of the Project under the California Environmental Quality Act (CEQA). Pursuant to comments regarding the Draft SEIR, which was published in September 2015, a Health Risk Assessment (HRA) has been prepared for the Project and is being added to the SEIR. Consistent with new modeling data used for the HRA, this technical Memo supplements Section 4.B of the Draft SEIR with an updated analysis of criteria pollutants emissions including reactive organic carbon (ROG), nitrogen oxides (NO_X), construction related exhaust particulate matter (PM), particulate matter with an aerodynamic diameter equal to or less than 10 microns (PM_{10}), particulate matter with an aerodynamic diameter equal to or less than 2.5 microns ($PM_{2.5}$), and carbon monoxide (CO).

This memo also discusses health effects of criteria pollutants along with the Project's potential cumulative health-related impacts pursuant to the *Sierra Club v. County of Fresno* court ruling.[1]

Consistent with the HRA, this analysis uses the updated and conservative assumptions about the timing of construction and the scope of project-related activity within the project area. For near-term activities, such as the first phase of construction, realistic assumptions are made based on the anticipated construction activity and phasing of development. For longer-term activities that may occur beyond the first phase of development, such as the development of commercial and retail space during phase 2, more conservative assumptions were made in order to provide a worst-case analysis of potential Project impact, because the actual construction activity and phasing of this development is currently unknown. These assumptions are provided in greater detail in Chapter 1 of this Memo.

For construction, this analysis shows the Project's criteria pollutant emissions are below the corresponding Bay Area Air Quality Management District (BAAQMD) significance thresholds except for NO_X emissions from Phase 1 construction. Phase 1 construction NO_X emissions are estimated to be an average of 55.7 pounds per day (lbs/day), exceeding the significance threshold of 54 lbs/day. Therefore, mitigation is required to reduce Project impacts during Phase 1 construction. As such, the Project Sponsor would require all off-road equipment greater than 50 horsepower to have engines that meet United States Environmental Protection Agency (USEPA) Tier 3 off-road emission standards. Implementation of this mitigation measure would reduce this impact to a less-than-significant level.

[1] Sierra Club v. County Of Fresno (Friant Ranch), S219783, Fifth Appellate District, F066798, Fresno County Superior Court.

For operations, Phase 1 operational activities are estimated to be an average of 54.60 pounds per day (lbs/day), exceeding the significance threshold of 54 lbs/day. Therefore, mitigation is required to reduce Project impacts during Phase 1 operations. As such, the Project would require all future tenants and building owners to use low-volatile organic compound (VOC) paints during maintenance activities. The VOC content of paints shall not exceed 10 grams of VOCs per liter. Implementation of this mitigation measure would reduce this impact to a less-than-significant level.

Because of the updated project details used in this analysis as compared to those used in the Draft SEIR (changes include square footage of some proposed land uses, and construction phasing and equipment fleets), the conclusions with regard to the project's criteria pollutants emissions have changed with this updated analysis. For example, conclusions about construction emissions changed from less than significant for all criteria pollutants in the Draft SEIR to less than significant with mitigation in this updated analysis (due to average daily unmitigated emissions during Phase 1 construction exceeding the BAAQMD threshold); the conclusions about project operational emissions have changed from significant and unavoidable impacts (attributable to average daily and total annual NO_X and PM_{10} emissions) during full buildout operations in the Draft SEIR to less than significant for all operational scenarios including the full buildout operations.

Please refer to Chapter 2, *Results*, for additional detail on the findings of this analysis.

CHAPTER 1
Health Effects of Criteria Pollutants

Certain air pollutants have been recognized to cause notable health problems and consequential damage to the environment either directly or in reaction with other pollutants, due to their presence in elevated concentrations in the atmosphere. Such pollutants have been identified and regulated as part of the overall endeavor to prevent further deterioration and facilitate improvement in air quality. The following pollutants are regulated by the USEPA and are subject to emissions control requirements adopted by federal, state and local regulatory agencies. These pollutants are referred to as "criteria air pollutants" as a result of the specific standards, or criteria, which have been adopted for them. National Ambient Air Quality Standards (NAAQS) and California Ambient Air Quality Standards (CAAQS) for each of the criteria air pollutants and their effects on health are summarized in the Draft SEIR (Table 4.B-2). It must be noted that the ambient air quality standards—both federal and state—are expressed as airborne concentrations of various pollutants. Compliance with the standards is on a regional basis. In the Bay Area, compliance is demonstrated by ongoing measurements of pollutant concentrations at more than 30 air quality monitoring stations operated by the BAAQMD in all nine Bay Area counties. An exceedance of an ambient air quality standard at any one of the stations counts as a regional exceedance.

NAAQS and CAAQS have been set at levels considered safe to protect public health, including the health of sensitive populations such as asthmatics, children, and the elderly with a margin of safety; and to protect public welfare, including protection against decreased visibility and damage to animals, crops, vegetation, and buildings. As explained by the California Air Resources Board (CARB), "An air quality standard defines the maximum amount of a pollutant averaged over a specified period of time that can be present in outdoor air without any harmful effects on people or the environment."[2] That is, if a region is in compliance with the ambient air quality standards, its regional air quality can be considered protective of public health. The NAAQS are statutorily required to be set by the USEPA at levels that are "requisite to protect the public health," 42 U.S.C. § 7409(b)(1).[3] As such, the closer a region is to attaining a particular NAAQS, the lower the human health impact is from that pollutant.

A brief description of the health effects of exposure to criteria air pollutants is provided below.

Ozone

Ground-level Ozone is the main component of smog. Ozone is a respiratory irritant and an oxidant that increases susceptibility to respiratory infections and that can cause substantial damage to vegetation and other materials. Ozone is not emitted directly into the atmosphere, but is a secondary air pollutant produced in the atmosphere through a complex series of photochemical reactions involving ROG and NO_X. ROG and NO_X are known as precursor compounds for ozone. Significant ozone production generally requires ozone precursors to be present in a stable atmosphere with strong sunlight for approximately three hours.

Ozone is a regional air pollutant because it is not emitted directly by sources, but is formed downwind of sources of ROG and NO_X under the influence of wind and sunlight. Ozone concentrations tend to be higher in the late spring, summer, and fall, when the long sunny days combine with regional subsidence inversions to create conditions conducive to the formation and accumulation of secondary photochemical compounds, like ozone.

According to the USEPA, ozone can cause the muscles in the airways to constrict potentially leading to wheezing and shortness of breath.[4] Ozone can make it more difficult to breathe deeply and vigorously; cause shortness of breath and pain when taking a deep breath; cause coughing and sore or scratchy throat; inflame and damage the airways; aggravate lung diseases such as asthma, emphysema and chronic bronchitis; increase the frequency of asthma attacks; make the lungs more susceptible to infection; continue to damage the lungs even when the symptoms have disappeared; and cause chronic obstructive pulmonary disease.[5] Long-term exposure to ozone is linked to aggravation of asthma, and is likely to be one of many causes of asthma development and long-term exposures to higher concentrations of ozone may also be linked to permanent lung damage, such as abnormal lung development in children.[6] According to the CARB, inhalation of ozone causes inflammation and irritation of the tissues lining human airways, causing and worsening a variety of symptoms and exposure to ozone can reduce the volume of air that the lungs breathe in and cause shortness of breath.[7] The USEPA states that people most at risk from breathing air containing ozone include people with asthma, children, older adults, and people who are active outdoors, especially outdoor workers.[8] Children are at greatest risk from exposure to ozone because their lungs are still developing and they are more likely to be active outdoors when

ozone levels are high, which increases their exposure.[9] According to CARB, studies show that children are no more or less likely to suffer harmful effects than adults; however, children and teens may be more susceptible to ozone and other pollutants because they spend nearly twice as much time outdoors and engaged in vigorous activities compared to adults.[10] Children breathe more rapidly than adults and inhale more pollution per pound of their body weight than adults and are less likely than adults to notice their own symptoms and avoid harmful exposures.[11] Further research may be able to better distinguish between health effects in children and adults.[12]

Nitrogen Dioxide

Nitrogen dioxide (NO_2) is an air quality pollutant of concern because it acts as a respiratory irritant. NO_2 is a major component of the group of gaseous nitrogen compounds commonly referred to as NOx. A precursor to ozone formation, NOx is produced by fuel combustion in motor vehicles, stationary sources such as industrial activities, ships, aircraft, and rail transit. Typically, NOx emitted from fuel combustion is in the form of nitric oxide and NO_2. Nitric oxide is often converted to NO_2 when it reacts with ozone or undergoes photochemical reactions in the atmosphere.

Ambient air quality standards have been promulgated for NO_2, which is a reddish-brown, reactive gas.[13] The principle form of NO_X produced by combustion is nitric oxide, but nitric oxide reacts quickly in the atmosphere to form NO_2, creating the mixture of nitric oxide and NO_2 referred to as NO_X.[14] Major sources of NO_X include emissions from cars, trucks and buses, power plants, and off-road equipment.[15] The terms NO_X and NO_2 are sometimes used interchangeably. However, the term NO_X is typically used when discussing emissions, usually from combustion-related activities, and the term NO_2 is typically used when discussing ambient air quality standards. Where NO_X emissions are discussed in the context of the thresholds of significance or impact analyses, the discussions are based on the conservative assumption that all NO_X emissions would oxidize in the atmosphere to form NO_2.

According to the USEPA, NO_2 can potentially irritate airways in the human respiratory system.[16] Short-term exposures can aggravate respiratory diseases, particularly asthma, leading to respiratory symptoms (such as coughing, wheezing or difficulty breathing), hospital admissions and visits to emergency rooms and longer exposures to elevated concentrations of NO_2 may

contribute to the development of asthma and potentially increase susceptibility to respiratory infections. According to CARB, controlled human exposure studies that show that NO_2 exposure can intensify responses to allergens in allergic asthmatics.[17] In addition, a number of epidemiological studies have demonstrated associations between NO_2 exposure and premature death, cardiopulmonary effects, decreased lung function growth in children, respiratory symptoms, emergency room visits for asthma, and intensified allergic responses.[18] Infants and children are particularly at risk from exposure to NO_2 because they have disproportionately higher exposure to NO_2 than adults due to their greater breathing rate for their body weight and their typically greater outdoor exposure duration while in adults, the greatest risk is to people who have chronic respiratory diseases, such as asthma and chronic obstructive pulmonary disease.[19] CARB states that much of the information on distribution in air, human exposure and dose, and health effects is specifically for NO_2 and there is only limited information for nitric oxide and NO_X, as well as large uncertainty in relating health effects to nitric oxide or NO_X exposure.[20]

Carbon Monoxide

Carbon monoxide is a non-reactive pollutant that is a product of incomplete combustion and is mostly associated with motor vehicle traffic. High CO concentrations develop primarily during winter when periods of light winds combine with the formation of ground level temperature inversions (typically from the evening through early morning). These conditions result in reduced dispersion of vehicle emissions. Motor vehicles also exhibit increased CO emission rates at low air temperatures. Unlike other criteria pollutants, whose effects are regional, CO impacts are evaluated locally. Localized areas where ambient concentrations exceed state and/or federal standards are termed CO hotspots.
