Introduction

This appendix documents measurement results from a pre-construction electromagnetic survey of locations along the San Francisco San Jose Project Section (Project Section, or project). The purpose of the survey was to: (1) provide a baseline characterization of the existing electromagnetic environment, (2) allow comparisons with the expected electromagnetic footprint from the planned California High-Speed Rail (HSR) System, and (3) provide guidance for electromagnetic compatibility requirements by defining the typical electromagnetic environment that the HSR system must operate in without interference.

Analysts reviewed land uses, existing facilities, and infrastructure along the alignment and evaluated a list of approximately 70 candidate sites. This review concentrated on identifying potentially electromagnetic interference (EMI)-sensitive facilities as well as existing electromagnetic field (EMF) sources such as power generation, power distribution, and communications facilities. The selection criteria, taken from Technical Memorandum (TM) 3.4.11, *Measurement Procedure for Assessment of CHSTP Alignment EMI Footprint* (Authority 2010), favored providing a balanced coverage of:

- The geographic extent of the segment
- High-emission sites
- Low-emission sites
- Sites with high-sensitivity receptors

A final group consisting of 14 sites was selected based upon the above considerations and to provide representative coverage of land uses. At each of these sites, analysts conducted two types of measurements—one measuring radiated electric fields and the second measuring background direct current (DC) and power frequency magnetic fields. To characterize the radio frequency (RF) environment, analysts measured radiated electric fields from 10 kilohertz (kHz) to 6 gigahertz (GHz) using an RF spectrum analyzer and calibrated antennas. Expected sources of RF signals include:

- Cell towers (cellular telephone)
- Broadcast towers (radio and television broadcasts)
- Airport radars and aircraft communications equipment
- General high-frequency and very-high-frequency fixed and mobile communications systems (e.g., police, fire, emergency medical technician, utilities, and government)
- Local wireless (wireless fidelity [WiFi] and Worldwide Interoperability for Microwave Access)

Analysts also measured background DC and power frequency magnetic fields along the alignment, and recorded these magnetic fields using a three-axis fluxgate sensor with a waveform recording data acquisition system. Expected sources of DC and low-frequency magnetic fields include:

- The geomagnetic field
- High-voltage transmission lines
- Electric distribution lines
- Traction power distribution facilities
- Geomagnetic perturbations due to passing vehicles and trains

The facilities most sensitive to shifts in the DC (geomagnetic perturbations) and alternating current (AC) magnetic fields are:

- High technology semiconductor (e.g., electron microscopes [transmission electron microscopes/scanning electron microscopes], electron-beam lithography, ion-writing systems, focused ion-beam systems)
- High technology biology (e.g., nuclear magnetic resonance, magnetic resonance imaging [MRI], and electron microscopes)
- Medical imaging (e.g., computed tomography [CT] scanners, MRI systems)

- University research (instrumentation for chemistry, physics, electrical engineering, and similar systems to those mentioned for high technology and medical facilities).

Test Procedures and Equipment

Analysts characterized the RF environment along the Project Section by measuring the prevailing electric field strength at each of 14 test sites, over the frequency range from 10 kHz to 6 GHz. The RF and magnetic field measurements were performed between July 18, 2016 and July 22, 2016. Measurements were made using a vertical monopole antenna (AH Systems SAS-550-1) for the frequency range from 10 kHz to 30 megahertz (MHz), and a broadband biological antenna (AH Systems SAS-521-7) for the frequency range from 25 MHz to 6 GHz, connected to an Anritsu MS2721B Spectrum Analyzer. Measurements were made in eight contiguous frequency bands and recorded per Section 6.4 of TM 3.4.11. Where practical, the RF antennas were located approximately 50 feet from the project alternatives.

Electric field measurement files from the spectrum analyzer include both min-hold and max-hold levels as a function of frequency across each of the measurement bands, and a complete file set will be preserved for each measurement location. Reported results include the low-frequency measurements with the omni-directional vertical monopole, plus measurements with the biological antenna in both horizontal and vertical positions, first facing the proposed alignment, and then in the direction that exhibited the maximum signal strength in each measurement band.

The magnetic field measurements characterized the prevailing background magnetic field levels as well as the temporal variations caused by the passing of trains on the existing right-of-way. Measurements were made at two positions at each site, separated by approximately 30 feet. The magnetic field measurements were performed using a pair of three-axis 5-gauss Bartington fluxgate sensors (bandwidth DC to 3 kHz), connected to National Instruments data acquisition system. Magnetic field waveforms were recorded so that DC and full frequency information is available over the entire sensor bandwidth.

Overview of the Measurement Results

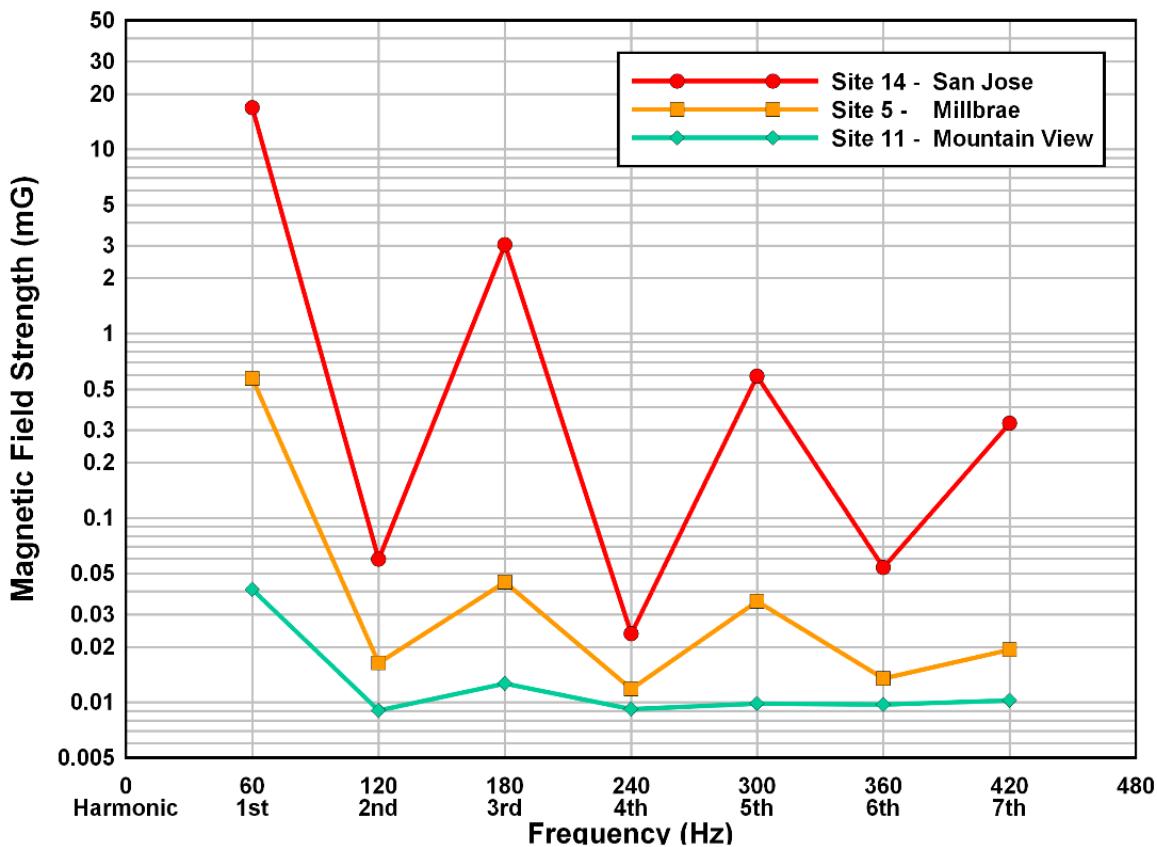

Magnetic Fields

The measured DC magnetic field strengths ranged from 310 to 500 milligauss (mG) across the 14 sites. At individual sites, the differences in field strength between the two sensors ranged from 0.4 to 79 mG. Site 10 (Urban Lane/Wells Avenue, Palo Alto) was the exception, showing a difference of 170 mG due to a steel fence very close to one of the magnetometers. For sites where the magnetometers were located close to the existing Caltrain tracks, fluctuations in DC level were distinctly noticeable during train passbys. At Site 9 (Fair Oaks Lane/Dinkelspiel Station Lane, Atherton) the magnetometers were approximately 16 feet from the nearest track centerline, and the DC levels changed roughly 50 mG during passbys. These fluctuations diminished rapidly with distance—at Site 3 (Bayshore Boulevard/Van Waters Road, Brisbane), fluctuations were on the order of 5 mG at 50 feet from the nearest track centerline, while fluctuations of just 2 mG were observed at Site 2 (Bayshore Boulevard/Valley Drive, Brisbane) at 65 feet from the nearest track centerline.

AC magnetic field strengths at the 14 sites varied over a range of more than two orders of magnitude, from 0.04 mG to 21 mG. The levels depend almost entirely on a site's proximity to power lines (medium-voltage distribution and high-voltage transmission lines) and other electrical system infrastructure. Such a range in observed magnetic field strengths is expected, due to the rapid decrease in magnetic field strength as you move away from these sources.

Figure 1 provides an illustration of the measured AC magnetic field strengths for three sites: a primarily residential area (Site 11, Franklin Street/Evelyn Avenue, Mountain View), a mixed residential and commercial area (Site 5, Monterey Street/Madrone Street, Millbrae), and an industrial area in close proximity to high-voltage transmission lines (Site 14, Montgomery/Ottersen Street, San Jose). These sites cover the full range of observed magnetic field strengths, with Site 11 the lowest, Site 14 the highest, and Site 5 representing the median

level. Levels are plotted for the 60-hertz (Hz) fundamental and the second through seventh harmonics. The large range of observed levels, which vary by nearly a factor of 400, is typical.

MARCH 2017

Figure 1 Maximum Magnetic Field Strengths for Three Representative Sites

Electric Fields

Because of the very broad range of frequencies of interest, the electric field measurements at each site were divided into eight overlapping frequency bands to provide adequate frequency resolution in each band. Table 1 summarizes the maximum magnitude of the measured electric field values, by frequency band for each survey site.

The resource study area (RSA) is highly developed and includes a large number of RF sources. Over 40 television and radio (AM and FM broadcast) transmitters were identified within 2 miles of the project alignment. In addition, there are hundreds of cellular communications towers and point-to-point microwave links operating in the region, as well as a significant number of intermittent fixed and mobile RF sources. This activity results in remarkably uniform and relatively high background levels within the RSA over much of the RF spectrum.

GHz = gigahertz

kHz = kilohertz

MHz = megahertz

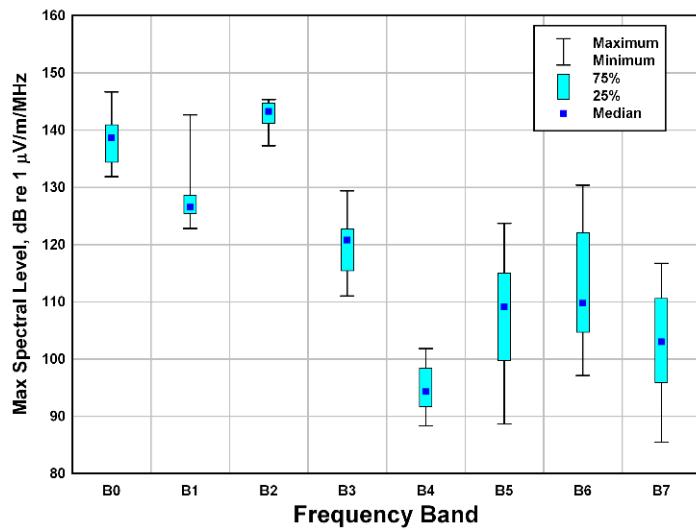

Field strength values are in decibels, referenced to 1 microvolt meter/MHz

Figure 2 graphically illustrates the maximum measured electric field strengths by frequency band for the 14 measurement sites, as well as the typical spectrum uses in each frequency band. Because of the well-developed nature of the region, the band-by-band measured field strengths were relatively consistent, with only a few sites falling more than 10 decibels from the mean in any given frequency band. Figure 3 illustrates the variance in RF field strengths across the 14 sites, by frequency band, and Figure 4 illustrates the maximum measured electric field strengths.

Figure 4 Maximum Measured Electric Field Strengths

Individual Site Observations

The following provides a brief summary of the EMF measurements conducted at each site. Complete measurement results are plotted and tabulated in Site Photographs and Measurement Data.

Site 1 (C Street/Owens Street, San Francisco)

This measurement site is in a heavily developed area adjacent to the existing Caltrain right-of-way, Interstate (I-) 280, and the University of California San Francisco Mission Bay Medical Center in the Mission Bay neighborhood of San Francisco. Overall magnitudes of DC magnetic fields at this site are influenced by nearby steel objects. The small DC field variations observed

were produced by passing vehicles on the closest side street that parallels I-280 and the alignment. Step (or fixed, as opposed to transient) changes in the DC magnetic field were recorded when parked vehicles come or go. No significant AC sources are nearby.

Visual identification of nearby RF emitters was hindered by the number and size of the adjacent buildings. However, maximum RF field strengths in the most active bands were controlled by AM broadcast stations (measurement band B2), FM broadcast stations (band B5), and cellular communications services (bands B6 and B7).

Site 2 (Bayshore Boulevard/Valley Drive, Brisbane)

Site 2 is in Brisbane at a relatively undeveloped site in the parking area behind the Brisbane Fire Station located at the intersection of Bayshore Boulevard and Valley Drive, near the Tunnel Avenue overpass. No significant AC or DC sources are nearby. Relatively low DC and AC magnetic fields were recorded at this site.

Site 3 (Bayshore Boulevard/Van Waters Road, Brisbane)

This measurement site is in Brisbane, in a relatively low-density industrial area off Bayshore Boulevard near the Brisbane Lagoon and the existing Caltrain tracks. This site was considered during site selection as a likely “quiet” site in terms of EMI. Brief spikes in DC magnetic field observed at this location are due to Caltrain passbys. No significant AC sources are nearby this measurement site.

Site 4 (Gateway Boulevard/Oyster Point Boulevard, South San Francisco)

Site 4 is in South San Francisco in a medium-density commercial/light-industrial area, within the parking lot at the Gateway Research Park, which includes operators of magnetically sensitive equipment. Analysts observed variations in DC data at this site due to passing vehicles moving in and out of the parking lot. Transmission lines are located south of the site, but these AC sources are far enough away that measured AC field strengths were quite low.

Site 5 (Monterey Street/Madrone Street, San Bruno)

This measurement site is in residential neighborhood near the San Francisco International Airport (SFO), adjacent to the Bay Area Rapid Transit (BART) system. Very large swings in DC fields were produced by the flow of traction currents from BART operations. The BART tracks pass this location in a tunnel heading toward the Millbrae Station, and there is a traction power substation located approximately 0.35 mile south of the measurement site. Local AC fields are mainly associated with high-voltage and medium-voltage overhead distribution lines along Madrone Avenue.

Site 6 (Trousdale Drive/California Drive, Burlingame)

Site 6 is in Burlingame, across from Burlingame Police Station and medical offices that operate MRI and CT imaging systems along Trousdale Drive. Changes in DC fields were due to Caltrain passbys and passing vehicles in the parking lot and along California Drive. AC fields were generated by an overhead distribution line running along California Drive.

Site 7 (Old County Road/Inverness Drive, San Carlos)

This measurement site is on a residential street in San Carlos, adjacent to the existing Caltrain tracks. Surrounding land uses are largely residential and light commercial in nature. The variation in DC fields at this location was caused by vehicle traffic on Old County Road. AC fields were generated by an overhead distribution line.

Site 8 (Arguello Street/Brewster Avenue, Redwood City)

This measurement site is in Redwood City in an office/commercial area, along Arguello Street, which runs parallel and adjacent to the existing Caltrain tracks. Across the street from the measurement site is a medical facility that focuses on radiology. Small, transient DC field variations were recorded at this location due to traffic, as well as with step changes due arrival of parked cars. AC fields were generated by overhead distribution lines.

Site 9 (Fair Oaks Lane/Dinkelspiel Station Lane, Atherton)

Site 9 is adjacent to the Atherton Caltrain Station southbound platform, on the west side of the Caltrain corridor. The Atherton Police Department is located nearby, but otherwise there are few RF emitters in the vicinity of this measurement site. Very strong DC field spikes were observed at this location due to passing Caltrain trains while AC fields, aside from transients caused by the passing trains, are less than 0.5 mG.

Site 10 (Urban Lane/Wells Avenue, Palo Alto)

Site 10 is behind the Palo Alto Medical Center adjacent to the existing Caltrain tracks. The DC magnetic field magnitude at the first sensor was reduced greatly by a nearby steel fence. DC field variations were produced by passing Caltrain trains. AC fields of approximately 1 mG were associated with an overhead distribution line.

Site 11 (Franklin Street/Evelyn Avenue, Mountain View)

This measurement site is in Mountain View, near a facility that houses both the Mountain View Fire Department and Police Station. The site is within a largely residential area, and is approximately 1,000 feet west of the Mountain View Caltrain Station. A few small DC field variations were recorded due to local vehicle traffic on Evelyn Avenue. AC fields were extremely low (less than 0.1 mG) because there are no nearby local AC sources.

Site 12 (Kifer Road/San Lucar Court, Sunnyvale)

Site 12 is in Sunnyvale, adjacent to an analytical instrumentation company in a light industrial area. DC variations were recorded associated with vehicle traffic accessing parking lots. AC fields were generated by overhead distribution lines at the back of the parking lot, adjacent to the Caltrain tracks.

Site 13 (Newhall Street/Newhall Drive, San Jose)

This measurement site was south of the Avaya Stadium in San Jose and approximately 0.25 mile east of the San Jose International Airport. The surrounding areas is mixed commercial and residential, and a small electrical substation is located immediately southeast of the measurement site. DC magnetic fields were quiet at this location. AC magnetic fields were due to overhead distribution lines. Magnetic fields show some variation due to varying load currents on the power lines, including a step change near the middle.

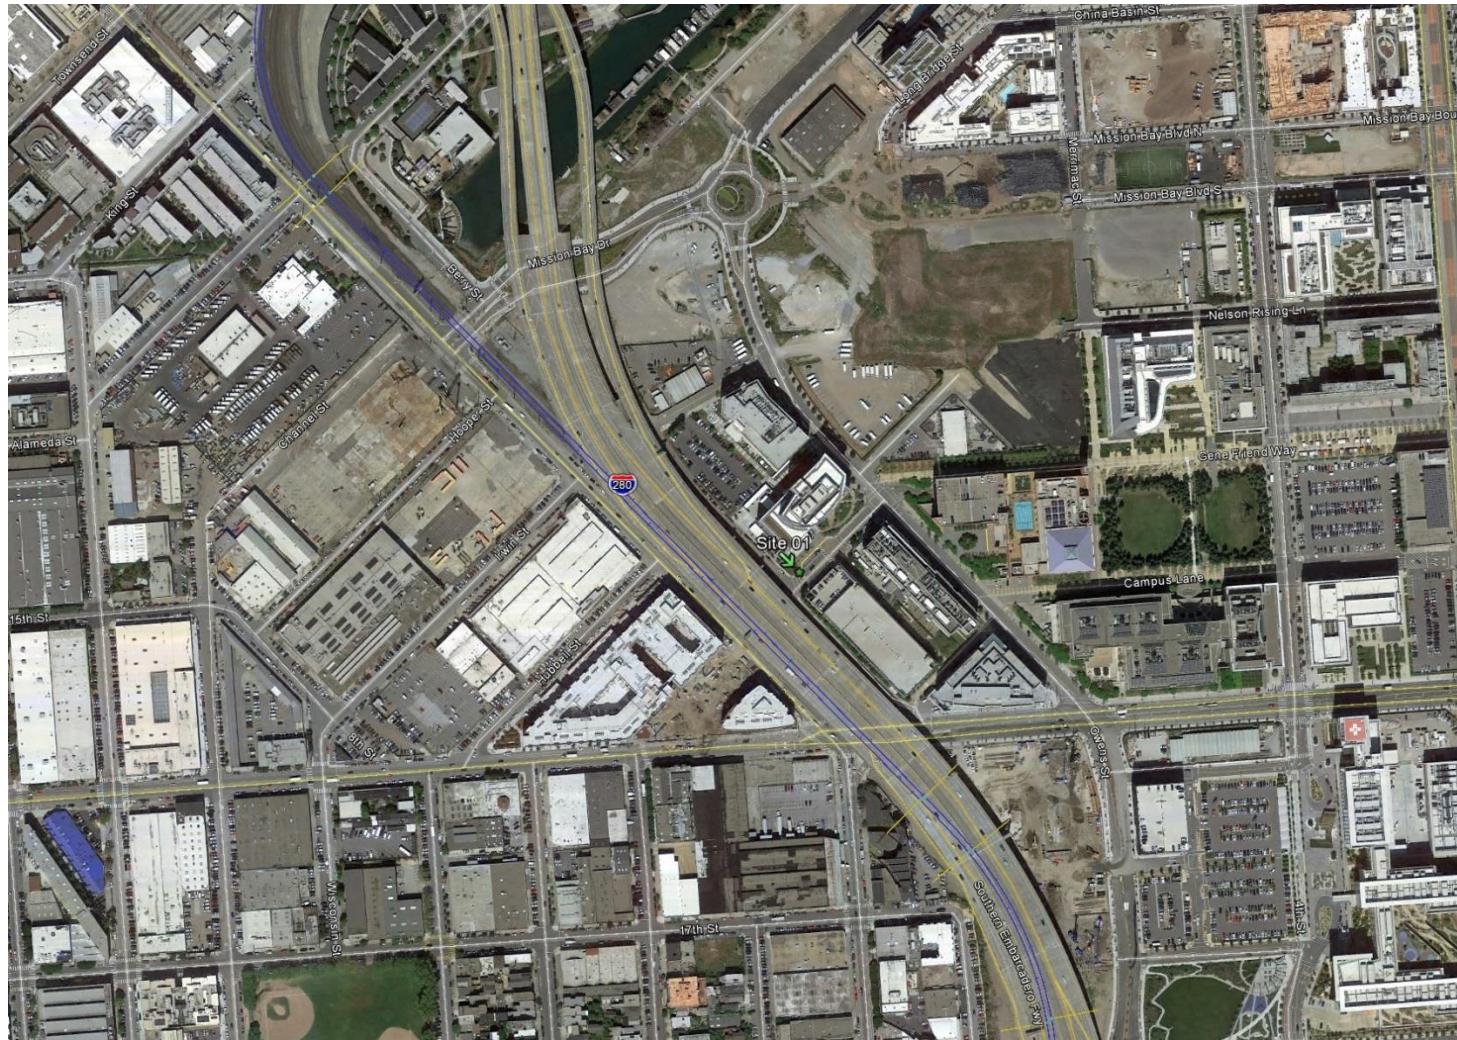

Site 14 (Montgomery Street/Otterton Street, San Jose)

This location was South of Diridon Station adjacent to the Pacific Gas and Electric Company (PG&E) Distribution Substation. Surrounding land uses are industrial and high-density residential, with numerous high-voltage and medium-voltage electrical distribution lines nearby. DC magnetic fields were relatively constant with very small variations. The first sensor had a total magnitude comparable to expected ambient, but the second was lower, indicating influence from nearby steel objects. Multiple trains moved along the alignment, but on the opposite side of the substation, they were sufficiently distant for the DC fluctuations to be quite small. AC magnetic fields in the 10–20 mG range are produced by the substation bus conductors and the power lines connected to the substation.

Site Photographs and Measurement Data

This section provides photographs and measurement results from each site. For each site, the following information is provided:

- Aerial location map identifying the measurement site
- Photographs of measurement site and views
- Measured DC and AC magnetic field strengths
- Measured environmental RF levels for Bands 0–4, Band 5, Band 6, and Band 7
