## Health Risk Assessment Background and Modeling Data

# 1. Construction Health Risk Assessment

---

## 1.1 INTRODUCTION

The Brea Mall—1065 Brea Mall, City of Brea—encompasses approximately 74 acres in northeast Orange County. As a result of the recent acquisition of the Sears parcel, the Simon Property Group (Simon Properties, or Applicant) is proposing redevelopment of that parcel and adjoining transition areas adjacent to Nordstrom and Macy's at the Brea Mall. The proposed redevelopment would be on an approximately 17.5-acre site ("project area") in the southwest portion of the Brea Mall. The Brea Mall is west of State Route 57 (SR-57) and is generally bounded by State College Boulevard to the east, Imperial Highway (State Route 90) to the south, South Randolph Avenue to the west, the City of Brea City Hall and Embassy Suites by Hilton to the northwest, and East Birch Street to the north.

In January 2020, the City issued a Draft Environmental Impact Report for the Brea Mall Mixed Use Project (SCH No. 20190800299) (DEIR), which proposed the redevelopment of an approximately 17.5-acre portion of the 73.8-acre Brea Mall. The redevelopment was triggered by the closure of Sears, one of the retail anchors at the mall, and the acquisition of the Sears parcel by Simon Properties, the majority landowner and operator of the Brea Mall, and project proponent. The DEIR analyzed the potential impacts of redeveloping the Sears parcel and immediately surrounding Mall property with a mixed-use project that would include new retail and restaurant spaces, for-rent residential apartments, a resort-type (lifestyle) fitness center, and a large central green which could be used as a plaza/gathering space for community events. The project proposed a net increase of 149,625 square feet of commercial square footage, and 312 residential units.

In March 2020, as a result of the Statewide restrictions imposed in response to the Covid-19 pandemic, including the temporary closure and subsequent limited re-opening of retail malls and restaurants within California, the project proponent requested that the application be placed on hold. In late 2020, the project proponent informed the City that they would like to continue processing its application, but that they had also made modifications to the proposed project and site plan in response to the changing retail, commercial and residential market.

The proposed project includes the same mix of retail, commercial, residential and recreational uses but on a slightly smaller scale and includes two options (Option 1 and Option 2) for development. Additionally, the footprint of the redevelopment work would cover approximately 15.5 acres, instead of the 17.5 acres. Under proposed project Option 1, there would be an increase of 85,425 square feet of new commercial uses and 390 apartment units; compared to a net increase of 149,625 square feet of new commercial uses and 312 units in the original application. Under proposed project Option 2, the lifestyle fitness would not be constructed. In its place, there would be a second residential building consisting of 280 multi-family units. Proposed project Option 2 would result in an overall reduction in commercial retail square footage and would reduce the amount of total commercial/retail square footage by 42,575 square feet and 670 units.

The proposed project would involve demolition, site preparation, grading, building construction, architectural coating, paving, and finishing and landscaping. The following provides the background methodology used for the construction health risk assessment for the proposed project.

Project construction would be phased over an approximately 40-month period for Option 1 and phased in over an approximately 66-month period for Option 2. Construction of either Option 1 or Option 2 is anticipated to commence in summer 2022. The nearest sensitive receptors to the project site are the single-family residences approximately 570 feet to the west fronting Pine Avenue. Guidance from the California Environmental Protection Agency (Cal/EPA), Office of Environmental Health Hazard Assessment (OEHHA), California Air Pollution Control Officers Association (CAPCOA), and the South Coast Air Quality Management District (South Coast AQMD) recommend the completion of health risk assessments (HRA) to determine the impacts of hazardous air emissions upon sensitive receptors in the vicinity of the project. As a result, a site-specific construction health risk assessment (HRA) has been prepared for the proposed project. This HRA considers the health impact to sensitive receptors (adults and children in the nearby residences) of construction emissions at the project site from diesel equipment exhaust (diesel particulate matter or DPM).

It should be noted that these health impacts are based on conservative (i.e., health protective) assumptions. The United States Environmental Protection Agency (USEPA, 2005) and the Office of Environmental Health Hazard Assessment (OEHHA, 2015) note that conservative assumptions used in a risk assessment are intended to ensure that the estimated risks do not underestimate the actual risks. Therefore, the estimated risks may not necessarily represent actual risks experienced by populations at or near a site. The use of conservative assumptions tends to produce upper-bound estimates of exposure and thus risk.

For residential-based receptors, the following conservative assumptions were used:

- It was assumed that maximum-exposed off-site residential receptors (both children and adults) stood outdoors and are subject to DPM at their residence for 8 hours per day, and approximately 260 construction days per year. In reality, California residents typically will spend on average 2 hours per day outdoors at their residences (USEPA, 2011). This would result in lower exposures to construction related DPM emissions and lower estimated risk values.
- The calculated risk for infants from third trimester to age 2 is multiplied by a factor of 10 to account for early life exposure and uncertainty in child versus adult exposure impacts (OEHHA, 2015).

## 1.2 METHODOLOGY AND SIGNIFICANCE THRESHOLDS

For this HRA, the South Coast AQMD significance thresholds were deemed to be appropriate and the thresholds that were used for this project are shown below:

- Excess cancer risk of more than 10 in a million
- Non-cancer hazard index (chronic or acute) greater than 1.0

The methodology used in this HRA is consistent with the following South Coast AQMD and the OEHHA guidance documents:

- OEHHA. 2015. *Air Toxics Hot Spots Program Guidance Manual for the Preparation of Health Risk Assessments*. February, 2015.

Potential exposures to DPM from proposed project construction were evaluated for off-site sensitive receptors in close proximity to the site. Pollutant concentrations were estimated using an air dispersion model, and excess lifetime cancer risks and chronic non-cancer hazard indexes were calculated. These risks were then compared to the significance thresholds adopted for this HRA.

## 1.3 CONSTRUCTION EMISSIONS

Construction emissions were calculated as average daily emissions in pounds per day, using the proposed construction schedule and the latest version of California Emissions Estimation Model, known as CalEEMod Version 2020.4 (CAPCOA, 2021). DPM emissions were based on the CalEEMod construction runs, using annual exhaust PM<sub>10</sub> construction emissions presented in pounds (lbs) per day.

Option 1 was assumed to take place over 40 months (870 workdays or 3.34 years) from the beginning of June 2022 through September 2025. Option 2 was assumed to take place over 66 months (1,435 workdays or 5.5 years) from the beginning of June 2022 through September 2025, continuing February 2026 through March 2028. The average daily emission rates from construction equipment used during the proposed project were determined by dividing the annual average emissions for each construction year by the number of construction days per year for each calendar year of construction (i.e., 2022 through 2028). The off-site hauling emission rates were adjusted to evaluate localized emissions from the 0.56-mile haul route within 1,000 feet of the project site. The CalEEMod construction emissions output and emission rate calculations are provided in Appendix A of the HRA.

## 1.4 DISPERSION MODELING

Air quality modeling was performed using the AERMOD atmospheric dispersion model to assess the impact of emitted compounds on sensitive receptors near the project. The model is a steady state Gaussian plume model and is an approved model by South Coast AQMD for estimating ground level impacts from point and fugitive sources in simple and complex terrain. The on-site construction emissions for the project were modeled as poly-area sources. The off-site mobile sources were modeled as adjacent line volume sources. The model requires additional input parameters, including chemical emission data and local meteorology. Inputs for the construction emission rates are those described in Section 1.3. Meteorological data obtained from the South Coast AQMD for the nearest representative meteorological station (Fullerton Airport) with the five latest available years (2012 to 2016) of record were used to represent local weather conditions and prevailing winds. The prevailing wind direction at the Fullerton Airport meteorological station is to the northeast, and the wind rose is provided in Appendix A.

The modeling analysis also considered the spatial distribution and elevation of each emitting source in relation to the sensitive receptors. To accommodate the model's Cartesian grid format, direction-dependent calculations were obtained by identifying the Universal Transverse Mercator (UTM) coordinates for each source location. In addition, digital elevation model (DEM) data for the area were obtained and included in the model runs to account for complex terrain. An emission release height of 4.15 meters was used as representative of the stack exhaust height for off-road construction equipment and diesel truck traffic, and an initial vertical dispersion parameter of 1.93 m was used, per California Air Resources Board (CARB) guidance (2000).

To determine contaminant impacts during construction hours, the model's Hour-By-Day-of-Week (HRDOW) scalar option was invoked to predict ground-level concentrations for construction emissions generated between the hours of 7:00 AM and 4:00 PM with a 1-hour lunch break.

A unit emission rate of 1 gram per second was used for all modeling runs. The unit emission rates were proportioned over the poly-area sources for on-site construction emissions and divided between the volume sources for off-site hauling emissions. The maximum modeled concentrations from the output files were then multiplied by the emission rates calculated in Appendix A to obtain the maximum flagpole-level concentrations at the off-site maximum exposed receptor (MER). As shown in Figure 1, the MER is a single-family residence west of the site along Pine Avenue. The MER location is the receptor location associated with the maximum AERMOD predicted DPM concentrations from the on-site emission source because the calculated on-site emission rates are approximately 2 to 3 orders of magnitude higher than the calculated off-site emission rates (see Appendix A). Therefore, the maximum concentrations associated with the on-site emission sources produce the highest overall ground-level MER concentrations and, consequently, highest calculated health risks.

The air dispersion model output for the emission sources is presented in Appendix B. The model output DPM concentrations from the construction emission sources are provided in Appendix C.

## 1.5 RISK CHARACTERIZATION

### 1.5.1 Carcinogenic Chemical Risk

Carcinogenic compounds are not considered to have threshold levels (i.e., dose levels below which there are no risks). Therefore, any exposure will have some associated risk. The South Coast AQMD has established a maximum incremental cancer risk of 10 in a million ( $1 \times 10^{-5}$  or  $10 \times 10^{-6}$ ) for CEQA projects and the OEHHA also sets a typical risk management level as 10 in a million (OEHHA, 2015).

Health risks associated with exposure to carcinogenic compounds can be defined in terms of the probability of developing cancer from exposure to a chemical at a given concentration. The cancer risk probability is determined by multiplying the chemical's annual concentration by its cancer potency factor (CPF), a measure of the carcinogenic potential of a chemical when a dose is received through the inhalation pathway. It is an upper-limit estimate of the probability of contracting cancer as a result of continuous exposure to an ambient concentration of one microgram per cubic meter ( $\mu\text{g}/\text{m}^3$ ), averaged over a lifetime of 70 years.

Recent guidance from OEHHA recommends a refinement to the standard point estimate approach with the use of age-specific breathing rates and age sensitivity factors (ASFs) to assess risk for susceptible subpopulations such as children. For the inhalation pathway, the procedure requires the incorporation of several discrete variates to effectively quantify dose for each age group. Once determined, contaminant dose is multiplied by the cancer potency factor in units of inverse dose expressed in milligrams per kilogram per day ( $\text{mg}/\text{kg}/\text{day}$ )<sup>-1</sup> to derive the cancer risk estimate. Therefore, the following dose algorithm was used to accommodate the unique exposures associated with each receptor type.

$$\text{Dose}_{\text{AIR,per age group}} = (\text{C}_{\text{air}} \times \text{EF} \times [\frac{\text{BR}}{\text{BW}}] \times \text{A} \times \text{CF})$$

Where:

Dose <sub>AIR</sub>	=	dose by inhalation ( $\text{mg}/\text{kg}\text{-day}$ ), per age group
C <sub>air</sub>	=	concentration of contaminant in air ( $\mu\text{g}/\text{m}^3$ )
EF	=	exposure frequency (number of days/365 days)
BR/BW	=	daily breathing rate normalized to body weight ( $\text{L}/\text{kg}\text{-day}$ )
A	=	inhalation absorption factor (default = 1)
CF	=	conversion factor ( $1 \times 10^{-6}$ , $\mu\text{g}$ to $\text{mg}$ , $\text{L}$ to $\text{m}^3$ )

The inhalation absorption factor (A) is a unitless factor that is only used if the cancer potency factor included a correction for absorption across the lung. The default value of 1 was used for this assessment. For residential receptors, the exposure frequency (EF) of 0.96 is used to represent 350 days per year to allow for a two-week period away from home each year (OEHHA, 2015). The 95<sup>th</sup> percentile daily breathing rates (BR/BW), exposure duration (ED), age sensitivity factors (ASFs), and fraction of time at home (FAH) for the various age groups are provided herein:

<u>Age Groups</u>	<u>BR/BW (L/kg-day)</u>	<u>ED</u>	<u>ASF</u>	<u>FAH</u>
Third trimester	361	0.25	10	0.85
0-2 age group	1,090	2	10	0.85
2-9 age group	861	7	3	0.72
2-16 age group	745	14	3	0.72
16-30 age group	335	14	1	0.73
16-70 age group	290	54	1	0.73

For construction analysis, the exposure duration spans the length of construction (e.g., 3.34 years for Option 1 and 5.5 years for Option 2). In addition, the construction duration each year was considered in the risk calculations to account for the number of days residents are exposed to construction emissions from 2022 through 2025 for Option 1 and 2022 through 2028 for Option 2. As the length of construction for either option is longer than 2.25 years, the third trimester, 0-2, and 2-9 age bins apply to the construction analysis for the off-site residential receptors.

To calculate the overall cancer risk, the risk for each appropriate age group is calculated per the following equation:

$$\text{Cancer Risk}_{\text{AIR}} = \text{Dose}_{\text{AIR}} \times \text{CPF} \times \text{ASF} \times \text{FAH} \times \frac{\text{ED}}{\text{AT}}$$

Where:

Dose <sub>AIR</sub>	=	dose by inhalation (mg/kg-day), per age group
CPF	=	cancer potency factor, chemical-specific (mg/kg-day) <sup>-1</sup>
ASF	=	age sensitivity factor, per age group
FAH	=	fraction of time at home, per age group (for residential receptors only)
ED	=	exposure duration (years)
AT	=	averaging time period over which exposure duration is averaged (70 years)

The CPFs used in the assessment were obtained from OEHHA guidance. The excess lifetime cancer risks during the construction period to the maximally exposed resident were calculated based on the factors provided above. The cancer risks for each age group are summed to estimate the total cancer risk for each toxic chemical species. The final step converts the cancer risk in scientific notation to a whole number that expresses the cancer risk in “chances per million” by multiplying the cancer risk by a factor of 1x10<sup>6</sup> (i.e., 1 million).

The calculated results are provided in Appendix C.

## 1.5.2 Non-Carcinogenic Hazards

An evaluation was also conducted of the potential non-cancer effects of chronic chemical exposures. Adverse health effects are evaluated by comparing the annual receptor level (flagpole) concentration of each chemical compound with the appropriate reference exposure limit (REL). Available RELs promulgated by OEHHA were considered in the assessment.

The hazard index approach was used to quantify non-carcinogenic impacts. The hazard index assumes that chronic sub-threshold exposures adversely affect a specific organ or organ system (toxicological endpoint). Target organs presented in regulatory guidance were used for each discrete chemical exposure. To calculate the hazard index, each chemical concentration or dose is divided by the appropriate toxicity value. This ratio is summed for compounds affecting the same toxicological endpoint. A health hazard is presumed to exist where the total equals or exceeds one.

The chronic hazard analysis for DPM is provided in Appendix C. The calculations contain the relevant exposure concentrations and corresponding reference dose values used in the evaluation of non-carcinogenic exposures.

## 1.6 CONSTRUCTION HRA RESULTS

The calculated results are provided in Appendix C and the results are summarized in Table 1.

TABLE 1. CONSTRUCTION RISK SUMMARY - UNMITIGATED

Receptor	Cancer Risk (per million)	Chronic Hazards
Maximum Exposed Receptor - Resident – Option 1	2.6	0.007
Maximum Exposed Receptor - Resident – Option 2	2.8	0.009
South Coast AQMD Threshold	10	1.0
<b>Exceeds Threshold?</b>	<b>No</b>	<b>No</b>

Note: Cancer risk calculated using 2015 OEHHA HRA guidance.

Cancer risk for the maximum exposed receptor from project-related construction emissions was calculated to be 2.6 in a million for Option 1 and 2.8 in a million for Option 2, which would not exceed the 10 in a million significance threshold. In accordance with the latest 2015 OEHHA guidance, the calculated total cancer risk conservatively assumes that the risk for the MER consists of a pregnant woman in the third trimester that subsequently gives birth to an infant during the construction period; therefore, all calculated risk values were multiplied by a factor of 10 for the first 2.25 years and by 3 for the remaining years. In addition, it was conservatively assumed that the residents were outdoors 8 hours a day and exposed to all of the daily construction emissions. For non-carcinogenic effects, the chronic hazard index identified for each toxicological endpoint totaled less than one for all the off-site sensitive receptors for both Option 1 and Option 2. Therefore, the project would not expose off-site sensitive receptors to substantial concentrations of air pollutant emissions during construction and impacts would be *less than significant*.

Although not needed to mitigate localized health risks, the following mitigation measure is proposed in the Draft Environmental Impact Report to reduce nitrogen oxide emissions:

**Mitigation Measure AQ-1:** The construction contractor(s) shall, at minimum, use equipment that meets the United States Environmental Protection Agency's (EPA) Tier 4 (Final) emissions standards for off-road diesel-powered construction equipment with more than 50 horsepower. Any emissions control device used by the contractor shall achieve emissions reductions that are no less than what

could be achieved by Tier 4 emissions standards for a similarly sized engine, as defined by the California Air Resources Board's regulations. Prior to construction, the project engineer shall ensure that all plans clearly show the requirement for EPA Tier 4 emissions standards for construction equipment over 50 horsepower for the specific activities stated above. During construction, the construction contractor shall maintain a list of all operating equipment associated with building demolition in use on the site for verification by the City. The construction equipment list shall state the makes, models, and numbers of construction equipment onsite. Equipment shall be properly serviced and maintained in accordance with the manufacturer's recommendations.

Mitigation Measure AQ-1 would further reduce the project's localized construction emissions, as shown in the following table. The results indicate that, with mitigation, the cancer risks and chronic hazard indices would be further reduced well below the South Coast AQMD's significance thresholds.

**TABLE 2. CONSTRUCTION RISK SUMMARY - MITIGATED**

Receptor	Cancer Risk (per million)	Chronic Hazards
Maximum Exposed Receptor - Resident – Option 1	0.3	0.001
Maximum Exposed Receptor - Resident – Option 2	0.4	0.001
South Coast AQMD Threshold	10	1.0
<b>Exceeds Threshold?</b>	<b>No</b>	<b>No</b>

Risks incorporate Mitigation Measure AQ-1, which includes using construction equipment which meets USEPA Tier 4 Final engine requirements for equipment over 50 horsepower.

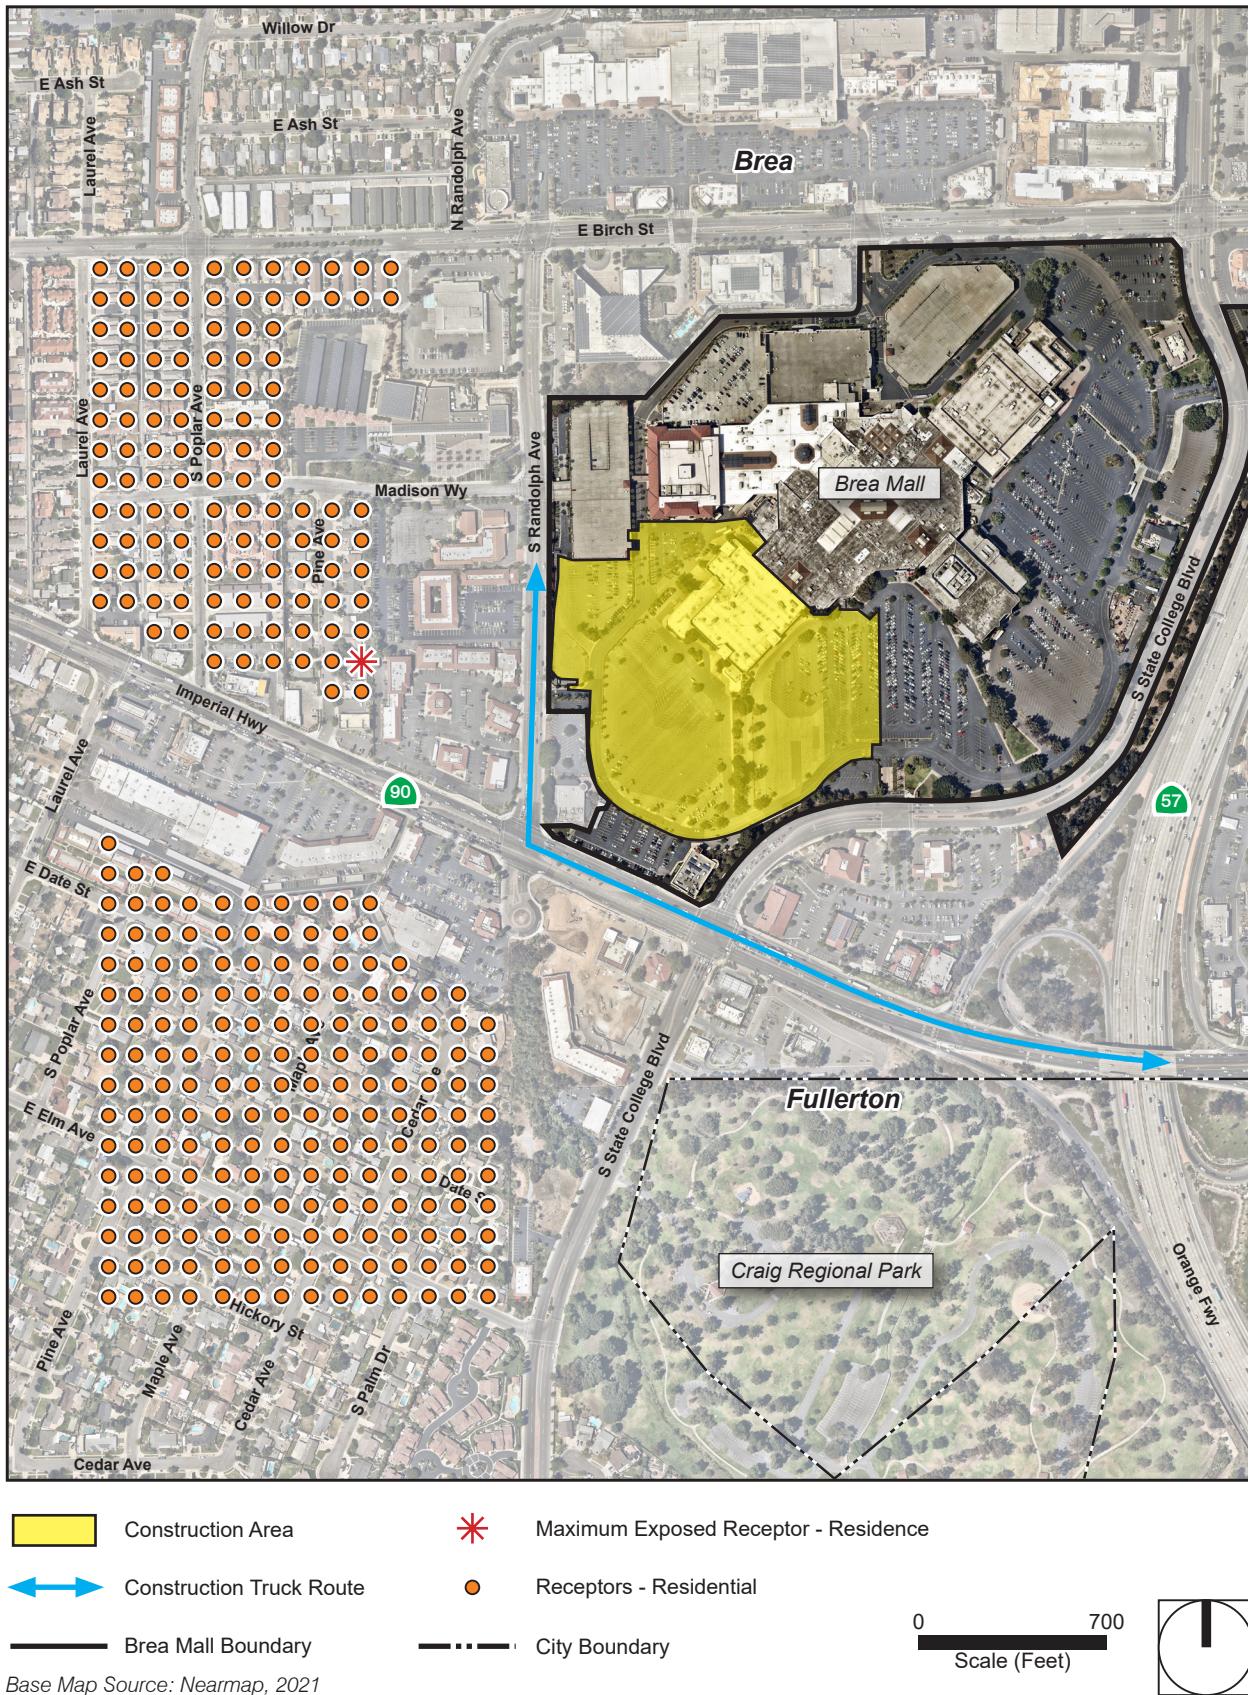

Note: Cancer risk calculated using 2015 OEHHA HRA guidance.

Note: Emissions evenly distributed over 47 modeled volume sources.

	Offsite	
Hauling Length (miles)	20.0	miles
Haul Length within 1,000 ft of Site (mile) <sup>3</sup>	0.56	miles
Hours per work day (7:00 AM to 4:00 PM, 1-hour of breaks) <sup>4</sup>	8	hours

<sup>1</sup> DPM emissions taken as PM<sub>10</sub> exhaust emissions from CalEEMod average daily emissions.

<sup>2</sup> Construction durations determined for each year to adjust receptor exposures to the exposure durations for each construction year (see App C - Risk Calculations).

<sup>3</sup> Emissions from CalEEMod offsite average daily emissions, which is based on proportioned haul truck trip distances, are adjusted to evaluate emissions from the 0.56-mile route within 1,000 of the project site.

<sup>4</sup> Work hours applied in By Hour/Day (HRDOW) variable emissions module in air dispersion model (see App C - Air Dispersion Model Output Files).
