## I. INTRODUCTION

The proposed project Jana Rd Commercial Development is a 4 acres site located on the southwest corner of Clinton Keith Rd & Jana Ln in the City of Wildomar, County of Riverside, State of California (see attached vicinity map). The site is currently undeveloped and bordered by commercial storage unit commercial development on its west and south borders. The proposed project contains a Foodmart 7250 sq feet, carwash tunnel 1790 sq ft, office warehouse with office 14,500 sq ft (3720 sq ft office) and two QSR 2000 and 1800 sq ft.

## II. DESCRIPTION OF THE EXISTING PRE-DEVELOPMENT ONSITE CONDITIONS

The subject site consists of a rectangular-shaped parcel, approximately 4 acres in size. The site is currently undeveloped. Ground surface cover consists of exposed soil and shrubs.

The site topography varies throughout the property. The site currently has a high point at approximately the northeast corner and the general drainage is from north to south, and slightly from east to west. Much of the existing topography drains into a storm drain channel. There is an estimated 14 feet of elevation differential across the site.

The project site will remain as one parcel to be developed into mix commercial. Phasing is not anticipated for this project. This hydrology report considers the project in its ultimate condition.

## III. POST DEVELOPMENT PROPOSED OFFSITE HYDROLOGY

The project will not receive any offsite flows per the offsite development of the surrounding streets along Jana Ln on the east or Clinton Keith Rd on the north. Offsite flows will also be directed around the site along the proposed curb and gutter along these streets. Water flow will continue south along Jana Ln to an existing catch basin into the existing storm drain line on Jana Ln.

## IV. POST DEVELOPMENT PROPOSED ONSITE HYDROLOGY

The proposed project generally maintains the existing drainage pattern. Runoff from the proposed development will be collected in an on-site catch basin and retained with the implementation of a Biofiltration system. Overflow from our system connects to an overflow storm drainpipe that runs through the southern part of the site towards the southeast corner.

The underground biofiltration system was evaluated and found to be an appropriate solution for the mitigation of the required quality volume. The on-site catch basin will be designed to capture drainage from the project site. The lowest pipe out of the system will direct flow to a storage tank the water will be directed into the WetlandMOD for filtration before going into an overflow pipe.

The initial size of the system was determined calculating the difference between the 100yr 24 hr Pre-Development flood volume – 100yr 24yr post-Development flood volume. This gave us the minimum storage size needed for the basin. Calculations using Civil Design could now be performed to test the size of the basin and confirm the basin would not overtop and the outflow would not exceed the pre-development condition.

Hydrologic calculations for the project were performed using CIVILCADD/CIVIL DESIGN Engineering Software, Version 7.1. Peak Flow and Time of Concentration values for each storm event were obtained for the pre-developed and post-developed condition using the “Riverside County Rational Hydrology Program option within the software, as preferred by the City of Wildomar.

The run-off index, time of concentration, pervious fraction and other pertinent information obtained from the rational analysis was then used to generate a post-development Unit Hydrograph for each respective drainage area, as applicable. This was done to compare the existing and proposed condition hydrology mitigation requirements for the rain events of 100-year design storms. The events were split up into 1 hr., 3 hr., 6 hr. and 24 hr. The Unit Hydrograph Analysis was performed using the CIVILCADD/CIVILDESIGN Engineering Software previously mentioned.

As appropriate, the resulting Unit Hydrograph was then imported into the CIVILCADD/CIVIL DESIGN Routing Software to perform basin routing and outflow analysis of each detention basin. The design of the basin follows the requirement to reduce post-development Q max to pre-development levels.

#### Design Parameters

- The drainage area is in Soil Group D according to the USDA NRCS Soil Survey.
- Antecedent Moisture Content (AMC) of I was used for 2-year and 5-year, II was used for 10-year and III was used for 100-year return frequency storm calculation.
- The onsite drainage area was analyzed for 10-year and 100-year storm event using Rational Method Analysis per Riverside County Hydrology Manual and CIVILCADD/CIVILDESIGN.
- The drainage area is located within a valley area.
- The rainfall depth of a 2-yr 1-hr storm event is 0.545 in. according to RCFC & WCD Plate D4-3.
- The rainfall depth of a 2-yr 3-hr storm event is 0.972 in. according to RCFC & WCD Plate D5-1.
- The rainfall depth of a 2-yr 6-hr storm event is 1.38 in. according to RCFC & WCD Plate D5-3.
- The rainfall depth of a 2-yr 24-hr storm event is 2.45 in. according to RCFC & WCD Plate D5-5.
- The rainfall depth of a 100-yr 1-hr storm event is 1.51 in. according to RCFC & WCD Plate D4-4.
- The rainfall depth of a 100-yr 3-hr storm event is 2.48 in. according to RCFC & WCD Plate D5-2.
- The rainfall depth of a 100-yr 6-hr storm event is 3.44 in. according to RCFC & WCD Plate D5-4.
- The rainfall depth of a 100-yr 24-hr storm event is 6.35 in. according to RCFC & WCD Plate D5-6.
- The impervious that was used for predevelopment is assumed to be 0%.
- The impervious that was used for Commercial subarea type is 90%.

#### V. CONCLUSION

The proposed project will increase the post Q amount compared to predevelopment levels. To mitigate this increase of flow coming from the project, a underground biofiltration system with the capacity to store up to a volume of 20,125 c.f. is being proposed. Routing of the flow through the basin did show a reduction of flow to predevelopment levels for all storm events.

Soil surveys contain information that affects land use planning in survey areas. They highlight soil limitations that affect various land uses and provide information about the properties of the soils in the survey areas. Soil surveys are designed for many different users, including farmers, ranchers, foresters, agronomists, urban planners, community officials, engineers, developers, builders, and home buyers. Also, conservationists, teachers, students, and specialists in recreation, waste disposal, and pollution control can use the surveys to help them understand, protect, or enhance the environment.

Various land use regulations of Federal, State, and local governments may impose special restrictions on land use or land treatment. Soil surveys identify soil properties that are used in making various land use or land treatment decisions. The information is intended to help the land users identify and reduce the effects of soil limitations on various land uses. The landowner or user is responsible for identifying and complying with existing laws and regulations.

Although soil survey information can be used for general farm, local, and wider area planning, onsite investigation is needed to supplement this information in some cases. Examples include soil quality assessments (<http://www.nrcs.usda.gov/wps/portal/nrcs/main/soils/health/>) and certain conservation and engineering applications. For more detailed information, contact your local USDA Service Center (<https://offices.sc.egov.usda.gov/locator/app?agency=nrcs>) or your NRCS State Soil Scientist ([http://www.nrcs.usda.gov/wps/portal/nrcs/detail/soils/contactus/?cid=nrcs142p2\\_053951](http://www.nrcs.usda.gov/wps/portal/nrcs/detail/soils/contactus/?cid=nrcs142p2_053951)).

Great differences in soil properties can occur within short distances. Some soils are seasonally wet or subject to flooding. Some are too unstable to be used as a foundation for buildings or roads. Clayey or wet soils are poorly suited to use as septic tank absorption fields. A high water table makes a soil poorly suited to basements or underground installations.

The National Cooperative Soil Survey is a joint effort of the United States Department of Agriculture and other Federal agencies, State agencies including the Agricultural Experiment Stations, and local agencies. The Natural Resources Conservation Service (NRCS) has leadership for the Federal part of the National Cooperative Soil Survey.

Information about soils is updated periodically. Updated information is available through the NRCS Web Soil Survey, the site for official soil survey information.

# How Soil Surveys Are Made

---

Soil surveys are made to provide information about the soils and miscellaneous areas in a specific area. They include a description of the soils and miscellaneous areas and their location on the landscape and tables that show soil properties and limitations affecting various uses. Soil scientists observed the steepness, length, and shape of the slopes; the general pattern of drainage; the kinds of crops and native plants; and the kinds of bedrock. They observed and described many soil profiles. A soil profile is the sequence of natural layers, or horizons, in a soil. The profile extends from the surface down into the unconsolidated material in which the soil formed or from the surface down to bedrock. The unconsolidated material is devoid of roots and other living organisms and has not been changed by other biological activity.

Currently, soils are mapped according to the boundaries of major land resource areas (MLRAs). MLRAs are geographically associated land resource units that share common characteristics related to physiography, geology, climate, water resources, soils, biological resources, and land uses (USDA, 2006). Soil survey areas typically consist of parts of one or more MLRA.

The soils and miscellaneous areas in a survey area occur in an orderly pattern that is related to the geology, landforms, relief, climate, and natural vegetation of the area. Each kind of soil and miscellaneous area is associated with a particular kind of landform or with a segment of the landform. By observing the soils and miscellaneous areas in the survey area and relating their position to specific segments of the landform, a soil scientist develops a concept, or model, of how they were formed. Thus, during mapping, this model enables the soil scientist to predict with a considerable degree of accuracy the kind of soil or miscellaneous area at a specific location on the landscape.

Commonly, individual soils on the landscape merge into one another as their characteristics gradually change. To construct an accurate soil map, however, soil scientists must determine the boundaries between the soils. They can observe only a limited number of soil profiles. Nevertheless, these observations, supplemented by an understanding of the soil-vegetation-landscape relationship, are sufficient to verify predictions of the kinds of soil in an area and to determine the boundaries.

Soil scientists recorded the characteristics of the soil profiles that they studied. They noted soil color, texture, size and shape of soil aggregates, kind and amount of rock fragments, distribution of plant roots, reaction, and other features that enable them to identify soils. After describing the soils in the survey area and determining their properties, the soil scientists assigned the soils to taxonomic classes (units).

Taxonomic classes are concepts. Each taxonomic class has a set of soil characteristics with precisely defined limits. The classes are used as a basis for comparison to classify soils systematically. Soil taxonomy, the system of taxonomic classification used in the United States, is based mainly on the kind and character of soil properties and the arrangement of horizons within the profile. After the soil

scientists classified and named the soils in the survey area, they compared the individual soils with similar soils in the same taxonomic class in other areas so that they could confirm data and assemble additional data based on experience and research.

The objective of soil mapping is not to delineate pure map unit components; the objective is to separate the landscape into landforms or landform segments that have similar use and management requirements. Each map unit is defined by a unique combination of soil components and/or miscellaneous areas in predictable proportions. Some components may be highly contrasting to the other components of the map unit. The presence of minor components in a map unit in no way diminishes the usefulness or accuracy of the data. The delineation of such landforms and landform segments on the map provides sufficient information for the development of resource plans. If intensive use of small areas is planned, onsite investigation is needed to define and locate the soils and miscellaneous areas.

Soil scientists make many field observations in the process of producing a soil map. The frequency of observation is dependent upon several factors, including scale of mapping, intensity of mapping, design of map units, complexity of the landscape, and experience of the soil scientist. Observations are made to test and refine the soil-landscape model and predictions and to verify the classification of the soils at specific locations. Once the soil-landscape model is refined, a significantly smaller number of measurements of individual soil properties are made and recorded. These measurements may include field measurements, such as those for color, depth to bedrock, and texture, and laboratory measurements, such as those for content of sand, silt, clay, salt, and other components. Properties of each soil typically vary from one point to another across the landscape.

Observations for map unit components are aggregated to develop ranges of characteristics for the components. The aggregated values are presented. Direct measurements do not exist for every property presented for every map unit component. Values for some properties are estimated from combinations of other properties.

While a soil survey is in progress, samples of some of the soils in the area generally are collected for laboratory analyses and for engineering tests. Soil scientists interpret the data from these analyses and tests as well as the field-observed characteristics and the soil properties to determine the expected behavior of the soils under different uses. Interpretations for all of the soils are field tested through observation of the soils in different uses and under different levels of management. Some interpretations are modified to fit local conditions, and some new interpretations are developed to meet local needs. Data are assembled from other sources, such as research information, production records, and field experience of specialists. For example, data on crop yields under defined levels of management are assembled from farm records and from field or plot experiments on the same kinds of soil.

Predictions about soil behavior are based not only on soil properties but also on such variables as climate and biological activity. Soil conditions are predictable over long periods of time, but they are not predictable from year to year. For example, soil scientists can predict with a fairly high degree of accuracy that a given soil will have a high water table within certain depths in most years, but they cannot predict that a high water table will always be at a specific level in the soil on a specific date.

After soil scientists located and identified the significant natural bodies of soil in the survey area, they drew the boundaries of these bodies on aerial photographs and

identified each as a specific map unit. Aerial photographs show trees, buildings, fields, roads, and rivers, all of which help in locating boundaries accurately.

## MAP INFORMATION

The soil surveys that comprise your AOI were mapped at 1:15,800.

Warning: Soil Map may not be valid at this scale.

Enlargement of maps beyond the scale of mapping can cause misunderstanding of the detail of mapping and accuracy of soil line placement. The maps do not show the small areas of contrasting soils that could have been shown at a more detailed scale.

Please rely on the bar scale on each map sheet for map measurements.

Maps from the Web Soil Survey are based on the Web Mercator projection, which preserves direction and shape but distorts distance and area. A projection that preserves area, such as the Albers equal-area conic projection, should be used if more accurate calculations of distance or area are required.

This product is generated from the USDA-NRCS certified data as of the version date(s) listed below.

Soil Survey Area: Western Riverside Area, California

Survey Area Data: Version 14, Sep 13, 2021

Soil map units are labeled (as space allows) for map scales 1:50,000 or larger.

Date(s) aerial images were photographed: Jan 7, 2021—Jan 14, 2021

The orthophoto or other base map on which the soil lines were compiled and digitized probably differs from the background imagery displayed on these maps. As a result, some minor shifting of map unit boundaries may be evident.

was impractical to make enough observations to identify all the soils and miscellaneous areas on the landscape.

The presence of minor components in a map unit in no way diminishes the usefulness or accuracy of the data. The objective of mapping is not to delineate pure taxonomic classes but rather to separate the landscape into landforms or landform segments that have similar use and management requirements. The delineation of such segments on the map provides sufficient information for the development of resource plans. If intensive use of small areas is planned, however, onsite investigation is needed to define and locate the soils and miscellaneous areas.

An identifying symbol precedes the map unit name in the map unit descriptions. Each description includes general facts about the unit and gives important soil properties and qualities.

Soils that have profiles that are almost alike make up a *soil series*. Except for differences in texture of the surface layer, all the soils of a series have major horizons that are similar in composition, thickness, and arrangement.

Soils of one series can differ in texture of the surface layer, slope, stoniness, salinity, degree of erosion, and other characteristics that affect their use. On the basis of such differences, a soil series is divided into *soil phases*. Most of the areas shown on the detailed soil maps are phases of soil series. The name of a soil phase commonly indicates a feature that affects use or management. For example, Alpha silt loam, 0 to 2 percent slopes, is a phase of the Alpha series.

Some map units are made up of two or more major soils or miscellaneous areas. These map units are complexes, associations, or undifferentiated groups.

A *complex* consists of two or more soils or miscellaneous areas in such an intricate pattern or in such small areas that they cannot be shown separately on the maps. The pattern and proportion of the soils or miscellaneous areas are somewhat similar in all areas. Alpha-Beta complex, 0 to 6 percent slopes, is an example.

An *association* is made up of two or more geographically associated soils or miscellaneous areas that are shown as one unit on the maps. Because of present or anticipated uses of the map units in the survey area, it was not considered practical or necessary to map the soils or miscellaneous areas separately. The pattern and relative proportion of the soils or miscellaneous areas are somewhat similar. Alpha-Beta association, 0 to 2 percent slopes, is an example.

An *undifferentiated group* is made up of two or more soils or miscellaneous areas that could be mapped individually but are mapped as one unit because similar interpretations can be made for use and management. The pattern and proportion of the soils or miscellaneous areas in a mapped area are not uniform. An area can be made up of only one of the major soils or miscellaneous areas, or it can be made up of all of them. Alpha and Beta soils, 0 to 2 percent slopes, is an example.

Some surveys include *miscellaneous areas*. Such areas have little or no soil material and support little or no vegetation. Rock outcrop is an example.

*Down-slope shape:* Concave

*Across-slope shape:* Linear

*Parent material:* Alluvium derived from granite

**Typical profile**

*H1 - 0 to 10 inches:* sandy loam

*H2 - 10 to 28 inches:* sandy clay loam

*H3 - 28 to 45 inches:* indurated

*H4 - 45 to 57 inches:* cemented

*H5 - 57 to 70 inches:* loamy coarse sand

**Properties and qualities**

*Slope:* 8 to 15 percent

*Depth to restrictive feature:* 20 to 39 inches to duripan

## Custom Soil Resource Report

*Drainage class:* Well drained  
*Runoff class:* High  
*Capacity of the most limiting layer to transmit water (Ksat):* Very low (0.00 to 0.00 in/hr)  
*Depth to water table:* More than 80 inches  
*Frequency of flooding:* None  
*Frequency of ponding:* None  
*Available water supply, 0 to 60 inches:* Low (about 4.1 inches)

<sup>1</sup> Precipitation frequency (PF) estimates in this table are based on frequency analysis of partial duration series (PDS).

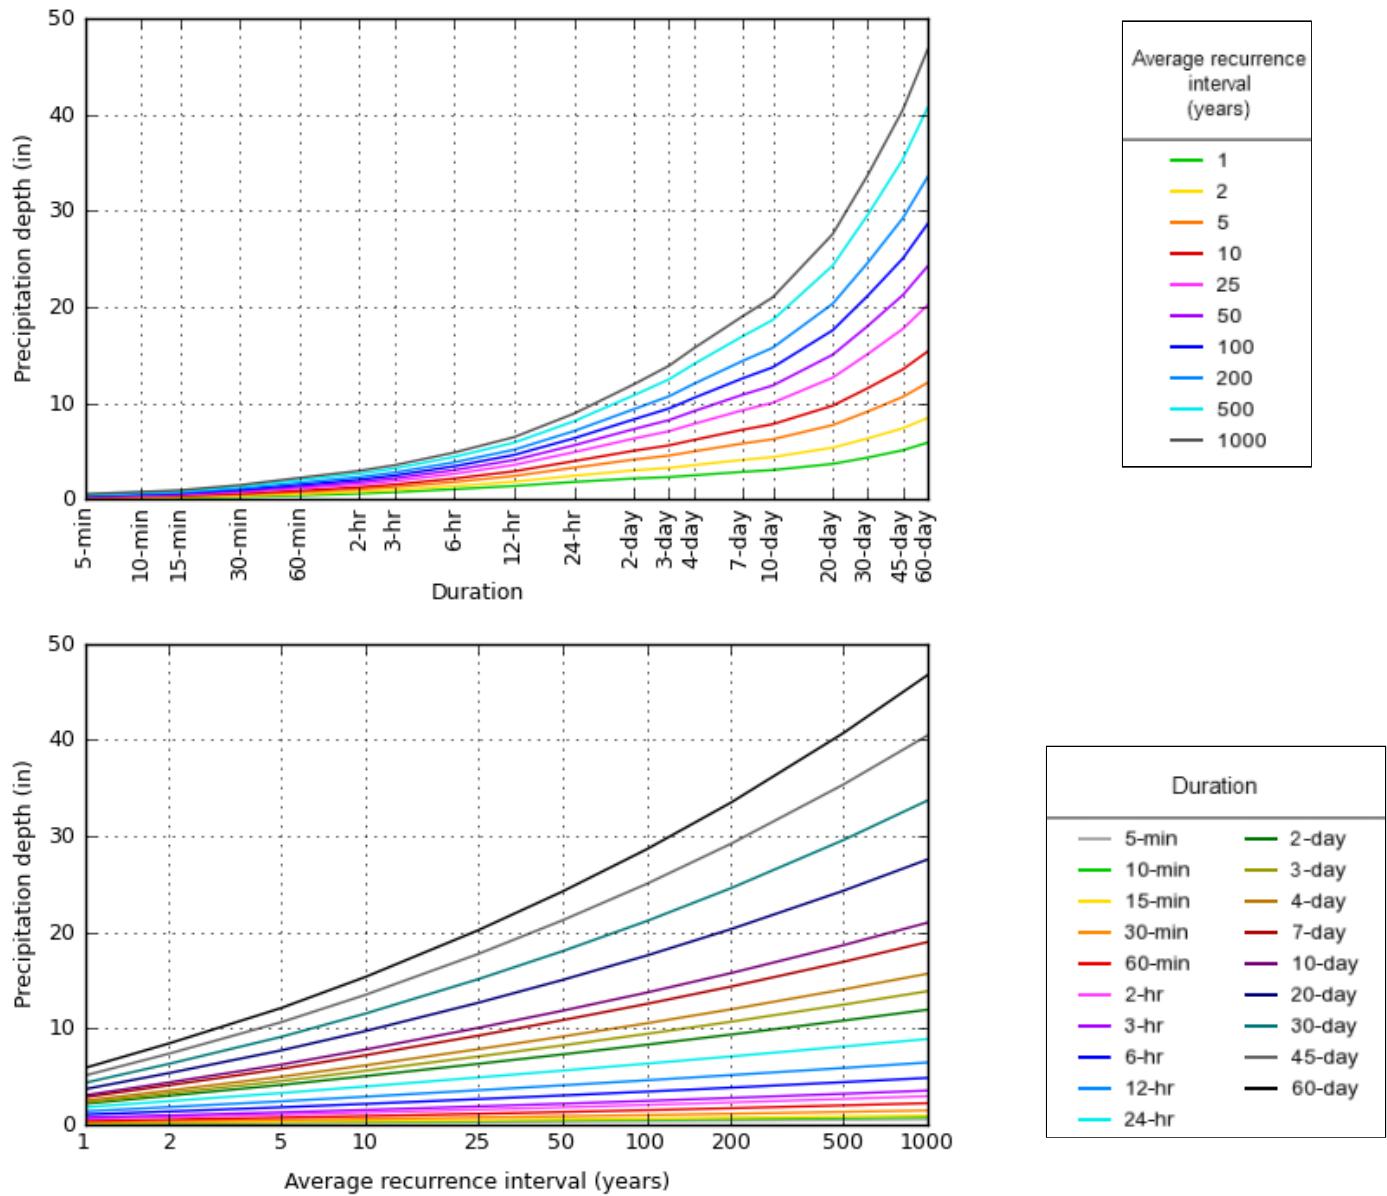

Numbers in parenthesis are PF estimates at lower and upper bounds of the 90% confidence interval. The probability that precipitation frequency estimates (for a given duration and average recurrence interval) will be greater than the upper bound (or less than the lower bound) is 5%. Estimates at upper bounds are not checked against probable maximum precipitation (PMP) estimates and may be higher than currently valid PMP values.
